15. Supplementary Notes Volume II of a six volume report. Volume III is published in six parts.		
16. Abstract A generalized and systematic effectiveness assessment methodology, including a computer program for quantifying the effectiveness of candidate system vessel combinations was developed. The methodology is described and guidelines for its use are presented. The results of applying this effectiveness assessment methodology to the 18 Wastewater Management System (WMS) concepts in configurations suitable for each of the six vessels included in this study are presented. The effectiveness model used is based on the following seven measures of effectiveness: Adaptability for Shipboard Installation, Performance, Operability, Personnel Safety, Habitability, Reliability, and Maintainability. Each effectiveness measure was successively broken down into constituent factors and subfactors, resulting in 111 individual criteria which were used as the basis for quantifying the effectiveness of each viable candidate system on each vessel. The effectiveness attribute data used are also presented.

ACKNOWLEDGEMENTS

This study was conducted under the technical direction of Mr. Thomas S. Scarano of the Office of Research and Development, U.S. Coast Guard. His suggestions for the goals of the study profoundly influenced its course and resulted in a generalization of the effectiveness assessment methodology. Mr. Scarano and Lt. Ed Magsig of the Office of Engineering, together with Mr. James A. White, of the Office of Research and Development provided valuable guidelines for and actively participated in the development of the effectiveness model used as the basis for quantifying the effectiveness of the candidate system/vessel combinations included in this study. Mr. Scarano also developed the weights for the measures of effectiveness and the associated factors and subfactors.

EFFECTIVENESS RATINGS FOR ELEMENTARY FACTORS/SUBFACTORS

1 - ADAPTABILITY FOR SHIPBOARD INSTALLATION	45
111 - Required black water handling capacity for vessel vs. actual capacity of WMS	45
112 - Required gray water handling capacity for vessel vs. actual capacity of WMS	46
12 - WMS materials disallowed or not recommended	47
13 - Extent of additional support systems or equipment required to accommodate WMS	48
21 - Extent of fixture modifications required for WMS installation	49
22 - Extent of flush medium supply modifications required for WMS installation	50
231 - Hookup requirements for WMS Collection/Transport subsystem installation	51
232 - Routing flexibility for drain piping modifications associated with WMS Collection/Transport subsystem installation	52
233 - Space requirements for WMS Collection/Transport subsystem installation	53
234 - Modularity of WMS Collection/Transport subsystem (as it affects installation)	54
235 - Vent requirements for WMS Collection/Transport subsystem installation	55
241 - Space requirements for WMS waste Treatment/Disposal subsystem installation	56
242 - Hookup requirements for WMS waste Treatment/Disposal subsystem installation	57
243 - Degree of modularity of WMS waste Treatment/Disposal (as it affects installation)	58
244 - Vent requirements for WMS waste Treatment/Disposal subsystem installation	59
245 - Exhaust stack requirements for WMS waste Treatment/Disposal subsystem installation	60
25 - Ease of installing WMS support equipment	61
26 - Ease of compensating for added weight of WMS	62

271 -	Extent of SHIPALTS (permanent modifications) required for WMS installation	63
272 -	Extent of temporary modification required for WMS installation	64
31 -	Effect of WMS on vessel stability	65
32 -	Effect of WMS on vessel trim and list	66
33 -	Effect of WMS on normal range of vessel	67
34 -	Degree of space trade-off/reallocation required for WMS installation	69
351 -	Amount of WMS consumption of vessel's electric power (relative)	70
352 -	Amount of WMS consumption of vessel's fuel oil (relative) .	71
353 -	Amount of WMS consumption of vessel's potable water (relative)	72
354 -	Amount of WMS consumption of vessel's compressed air (relative)	73
355 -	Amount of WMS consumption of cooling water (relative) ...	74
II -	PERFORMANCE	75
11 -	WMS per capita energy consumption (relative)	75
12 -	WMS per capita wet weight (relative)	76
13 -	WMS per capita volume (relative)	77
21 -	Adequacy of WMS black water holding times	78
22 -	Adequacy of WMS gray water holding times	79
311 -	Effect of peak hydraulic loads in black water stream on WMS performance	80
312 -	Effect of peak hydraulic loads in gray water streams on WMS performance	82
321 -	Effect of low flow conditions/long idle times in black water stream on WMS performance	84
322 -	Effect of low flow conditions/long idle times in gray water stream on WMS performance	86

331 - Ability of black water portion of WMS to handle additional personnel (on a long-term basis)	87
332 - Ability of gray water portion of WMS to handle additional personnel (on a long-term basis)	89
41 - Ability of black water handling portion of WMS to operate for sustained time periods	91
42 - Ability of gray water handling portion of WMS to operate for sustained time periods	92
51 - Ability of WMS to handle ground garbage in black water stream	93
52 - Ability of WMS to handle foreign materials/objects in black water stream	94
53 - Ability of WMS to handle detergents/surfactants in black water stream	96
54 - Ability of WMS to handle toxic materials in black water stream	97
61 - Ability of WMS secondary emissions to meet applicable standards for the discharge of air pollutants	98
62 - WMS potential for producing oil contaminated residues at sea	99
71 - Performance risk for black water handling portion of WMS ...	100
72 - Performance risk for gray water handling portion of WMS	102
 III - OPERABILITY	 104
11 - Degree of automation for WMS operation	104
12 - Ease of disposal of WMS residue(s)	106
13 - Ease of WMS mode changeovers (relative)	108
14 - Likelihood of violating effluent standards because of procedural errors in WMS operation	109
21 - Frequency of WMS operator attention required (relative)	111
22 - Number of man-hours of operator attention for WMS (relative)	112
23 - Skill level requirements for operators of WMS	113
24 - Training requirements for operators of WMS	114

25 -	Effect of WMS operation on vessel work routines/schedules	115
26 -	Additional personnel (billets) requirements for WMS operation	116
31 -	Amount of consumables/expendables required for WMS operation (relative)	117
32 -	Availability of specialized or unique/consumables/expendables required for WMS operation	118
33 -	Operating requirements for special or unique WMS support equipment	120
IV -	PERSONNEL SAFETY	122
11 -	Hazard of contact with/spillage of toxic/dangerous substances due to inherent WMS design	122
12 -	Hazard of contact with spillage of toxic/dangerous substances due to procedural errors/equipment failures of WMS	124
21 -	Hazard of explosive potential for operator/maintainer due to inherent WMS design	126
22 -	Hazard of explosive potential for operator/maintainer due to procedural error/equipment failures of WMS	128
31 -	Hazard of fire ignition potential due to inherent WMS design	130
32 -	Hazard of fire ignition potential due to procedural errors/equipment failure of WMS	132
4 -	Hazard of electric shock potential for operator/maintainer of WMS	134
51 -	Physical hazards associated with WMS due to sharp edges	136
52 -	Physical hazards associated with WMS due to hot surfaces	138
53 -	Physical hazards for WMS maintainer due to rotating machinery	140
V	HABITABILITY	142
11 -	Habitability problems associated with bacterial contamination due to WMS inherent design	142
12 -	Habitability problems associated with bacterial contamination due to procedural errors/equipment failures of WMS	143
21 -	WMS fixture comfort	145

22 - Flushing procedure requirements for WMS fixtures	146
23 - Waste retention in WMS commode bowl	147
24 - Likelihood of user contact with WMS fixture flushing medium	148
25 - Appearance of WMS fixture flushing medium	149
26 - Noise produced in flushing WMS fixtures	150
31 - Odors produced as a result of inherent WMS design	151
32 - Odors produced as a result of procedural errors/equipment failures of WMS	152
41 - Heat generation for nearby personnel due to inherent design	153
42 - Heat generation for nearby personnel due to procedural errors/equipment failures of WMS	155
5 - Noise level for personnel in vicinity of WMS	157
6 - Vibration levels for nearby personnel produced by WMS machinery	159
7 - Effect of WMS on user housekeeping routines	161
 VI - RELIABILITY	 163
1 - Failure frequency index for WMS (relative)	163
21 - WMS complexity	164
22 - Extent of WMS configuration redundancy	165
23 - Extent of WMS equipment/component redundancy	167
24 - Degree of equipment failure independence	169
25 - Adequacy of WMS equipment ratings	171
26 - Provisions for fault-actuated cut-off mechanisms for WMS protection	173
3 - Reliability risk for WMS	175

VII - MAINTAINABILITY	177
1 - Frequency of WMS corrective maintenance (CM) actions (failure frequency - relative)	177
2 - Man-hour and skill level requirements for WMS CM actions (relative)	178
131 - Accessibility of replaceable WMS components	179
132 - Extent of WMS modularization for ease of repair/replacement	181
133 - Degree of WMS repairability on board vessel	182
134 - Availability of manufacturer field and training programs for WMS	183
141 - Extent of spares stockage required for WMS equipment repairs (relative)	184
142 - Special/proprietary item requirements for WMS equipment repair	185
21 - Frequency of PM actions (relative)	186
22 - Man-hours required for WMS PM actions (relative)	187
23 - Effect of WMS PM on vessel watchstander routines	188

INTRODUCTION

OBJECTIVES

There are two main objectives of the effectiveness analysis. The first objective is the development of a generalized methodology for assessing the effectiveness of candidate system/vessel combinations. Fulfillment of this objective requires that the methodology have the following properties:

- . Ability to address all issues which are considered to be pertinent to an effectiveness assessment in general, and in particular to the specific candidate systems and vessels being considered.
- . Ability to accommodate both quantitative and qualitative data pertaining to candidate system/vessel combinations as well as relevant assumptions and constraints.
- . Ability to accommodate subjective judgements of the decision-maker.
- . Consistency between the level of detail of the analysis and data availability. This property requires that while full use should be made of all system/vessel data which is either available or can readily be made available, data which cannot be obtained within the confines of the study should not be called for.
- . Ability to provide quantitative results, preferably at several levels of detail, to facilitate making comparisons and trade-offs. However, the quantitative results should be transparent to user, i.e., readily interpretable in terms of the system/vessel properties, the objectives, requirements, constraints, etc.

The second objective is the application of the effectiveness assessment methodology to the viable candidate system/vessel combinations included in this study. The results of this application could in turn be

used to study the cost versus effectiveness relationship of the candidates in order to choose an optimum, i.e., most cost-effective candidate system for each vessel class.

SCOPE OF EFFECTIVENESS ANALYSIS

The effort under this portion of the study includes the following:

- . Development and documentation of a generalized effectiveness modeling and assessment methodology.
- . Development and documentation of a generalized computer program for quantifying the effectiveness of candidate system/vessel combinations.
- . Development of an effectiveness model suitable for analyzing candidate wastewater management systems (WMS) for selected U.S. Coast Guard vessels. The candidate systems are intended for managing the black (output from commodes, urinals and garbage grinder) and gray (galley and turbid, i.e., output from sinks, showers, laundry, deck, drains, etc.) wastewaters aboard the vessels.
- . Development and documentation of the effectiveness attribute data required as input to the effectiveness model.
- . Exercise the effectiveness model by substituting the data and developing quantitative effectiveness assessments for all viable candidate system/vessel combinations.

Systems and Vessels Analyzed

The systems and vessels considered for the effectiveness quantification are the 18 WMS concepts in configurations suitable for each of the six vessels included in this study (see Volume IV). Of these, effectiveness attribute data were developed and results obtained only for those system/vessel combinations which were judged to be viable candidates on the basis of the installation analysis (see Volume III).

General Applicability of the Effectiveness Assessment Methodology

Although specific results were obtained for the viable candidate system/vessel combinations included in this study, both the concepts and the procedural steps of the effectiveness modeling and quantification methodology developed as part of this study are general and have wide applicability. Specifically, this methodology is applicable to any type of problem which can be cast in the context of choosing an optimum (i.e., most cost-effective) candidate from a number of available legitimate alternatives. These alternative candidates do not necessarily have to be systems. Thus, the candidates may be alternative choices of processes or (e.g., chemical), alternative approaches to solving a problem, etc.

Furthermore, the computer program for quantifying effectiveness was not written for any one specific effectiveness model. Instead, the effectiveness model (and its associated data) are part of the input. As a result, this computer program is capable of handling any type of problem as soon as the necessary inputs have been developed.

Limitations

The effectiveness ratings presented herein are applicable to the specific systems and vessels included in this study. Furthermore, these results reflect the assumptions, objectives, requirements and constraints which are part of the context of this study. As a result, caution is advised in attempting to use these results directly for systems and/or vessels others than those specifically included in this study, or in a different context.

The effectiveness ratings are subject to the following considerations. The effectiveness attributes used as the basis for the ratings are a mixture of objectively determined system/vessel characteristics as well as subjectively determined qualitative system/vessel characteristics based on the analysis of the marine sanitary devices (MSDs) and the candidate WMS systems which we hybridized from these MSD subsystems, (see data in Volumes I, III and V).

In addition, the elements of the effectiveness model, especially the weight assignment and the effectiveness rating functions are based on subjective judgements. As a result, if one agrees with these judgements as well as the data used, then one may also accept the validity of the results. On the other hand, if one has reservations about the accuracy of the data and/or strongly disagrees with the subjective judgements inherent in the effectiveness model, then one may question the validity of the results. In such cases, one can substitute different data and/or subjective judgements, assumptions, etc., and obtain a new set of results (at least in principle, even if one may not actually wish to do this). In either case, the data, the subjective judgements, the assumptions, etc., used are all documented and are accessible. Another relevant point to keep in mind is that the effectiveness ratings are not to be used in an absolute sense but rather as a means of comparing candidate systems for the purpose of discerning differences among the alternatives available. In this connection, it is noted that since the same effectiveness model is used to assess the candidate systems and the same generic MSD subsystem/equipment data is used for all system/vessel combinations, all candidates are treated equally. Hence, bias (to be distinguished from subjective judgement) in the results is avoided.

ASSUMPTIONS

The assumptions which govern the effectiveness analysis of the candidate system/vessel combinations are primarily those which were used in the development of the effectiveness attribute data and the development of the effectiveness model. The assumptions pertaining to the effectiveness attribute data are documented in Volumes V and III for the MSD effectiveness attribute data and for the WMS installation effectiveness attribute data, respectively. Assumptions pertinent to the effectiveness model are primarily those used in the development of the effectiveness rating functions (ERFs) and appear as part of the ERF documentation.

APPROACH

The approach used in the development of the effectiveness analysis methodology and its application to the candidate system/vessels combinations included in this study is discussed briefly below.

Development of the Effectiveness Assessment Methodology

The basic concepts which form the basis of this effectiveness assessment methodology are not new and there are a number of precedents for their use. A prior application* of these concepts might be described as the development of the underlying philosophy and theory of the approach to the status of an art. The main objective of this effort was a refinement of this effectiveness analysis approach and additional development (and documentation) of the procedural aspects of the approach, leading to a general and well defined methodology with clearly identifiable steps.

The effectiveness assessment methodology is the system of analysis techniques and associated computational procedures which start with the relevant information concerning the candidates and their associated context as an input, and generated quantitative effectiveness ratings as an output. This methodology consists of procedures, guidelines and computational aids for executing the following three main steps of the effectiveness assessment.

- . Development of the effectiveness model
- . Development of effectiveness attribute data geared to the effectiveness model.
- . Quantification of effectiveness.

* S. Orbach and R. Field, "Cost Effectiveness Study of Selected Marine Sanitary Devices; Effectiveness Assessment," Phase II Final Report, NSRDC Report 4426, September 1974, Contract N00600-72-D-0613, Conducted by Bradford National Corporation and NSRDC.

The development of the effectiveness model consists of the following identifiable steps:

- . Selection of a set of measures of effectiveness (M/Es). The M/Es constitute a set of highest level overall criteria which will be the basis for assessing the effectiveness of the candidates.
- . Assignment of M/E weights. These M/E weights are used to indicate the importance of each M/E in relation to the others.
- . Determination of the factors and subfactors of each M/E.
Factors result from a breakdown of an M/E into its constituent lower level subordinate criteria which are implied by the higher level criterion represented by the given M/E. Subfactors result from a breakdown of a factor or another subfactor into its constituent lower level subordinate criteria which are implied by the higher level criterion represented by the given factor or subfactor. Elementary factors or subfactors are those which have no subordinate subfactors and which can be directly related to one or more attributes of the candidates under consideration.
- . Assignment of factor/subfactor weights. These weights are used to indicate the importance of each factor/subfactor (i.e., criterion) in relation to the others at the same level of subordination.
- . Development of an effectiveness rating function (ERF) for every elementary factor/subfactor. An ERF constitutes a functional relationship between the candidate attribute (characteristic) relevant to the given elementary factor/subfactor and an effectiveness rating which is a quantitative measure of the candidate's acceptability, quality, worth, etc., with respect to the given criterion. The ERFs constitute an important element of the effectiveness model. They provide a mechanism for systematically bringing together and integrating the essential elements of the effectiveness assessment, namely:

- .. Assumptions, goals, requirements and constraints.
- .. Technical information
- .. Subjective judgements of the decision maker

The effectiveness attribute data required is determined by the ERFs. The ERFs also determine the format of these data and a numbering scheme which uniquely identifies each ERF within each M/E is used to associate the data with the corresponding ERF. An important aspect of the development of the ERFs and the associated effectiveness attribute data is its flexibility with respect to the type and level of detail of the required data. This ensures that the data requirements are realistic and are consistent with common practice in the field, i.e., the analyses performed in support of the effectiveness assessment such as MSD analysis, installation analysis, life cycle cost analysis, etc. Thus, the development of effectiveness attribute data represents another important mechanism for integrating the results of the various analyses which are normally performed in the course of studying the candidates.

The quantification of the effectiveness is accomplished by relating the rating at any level of subordination in the effectiveness model to the next lower level elements of the model as the sum of products of the ratings and associated weights of these elements. Thus, starting with the elementary factors/subfactors, the next higher level subfactor or factor ratings are given as the sum of products of the elementary factors/subfactors. Similarly, the rating for a given M/E is obtained as the sum of products of its factor ratings and their associated weights. Finally, the overall effectiveness rating is obtained as the sum of the products of M/E ratings and their associated weights. Once the effectiveness model and the associated effectiveness attribute data have been developed, the quantification of effectiveness is fairly straightforward and is accomplished by a computer program. The output of the computer program consists of an overall effectiveness rating for each candidate as well as effectiveness ratings with respect to each M/E.

As part of the development of the effectiveness assessment methodology, the above steps have been documented in greater detail and guidelines for executing these steps have been included (see "Discussion of the Effectiveness Assessment Methodology and Application Guidelines").

A summary of the methodology is presented in Figure 1 which shows the three main steps of the procedure namely, development of the model, use of effectiveness attribute data and quantification of effectiveness. It is noted both from the previous discussion of the development of the elements of the effectiveness model and from Figure 1 that the M/Es, the factor/subfactors and their associated levels of subordination constitute a hierarchy. Actually, four types of hierarchies can be discerned in connection with the effectiveness assessment methodology, namely:

- A hierarchy of objectives and requirements.
- A hierarchy of criteria associated with the objectives and requirements.
- A hierarchy indicating the importance of each criterion in relation to the others.
- A hierarchy of effectiveness ratings which are quantitative measures of the degree to which each criterion in the hierarchy is satisfied by each candidate.

The first three hierarchies are associated with the effectiveness model and the last hierarchy is associated with the quantification of effectiveness. However, it is noted from Figure 1 that the quantification of effectiveness includes the use of the weights. Thus, the weights possess a dual character, namely, as indicators of the importance of the relative importance of each criterion (related to the effectiveness model), and as numbers used in obtaining the ratings (related to the quantification process). Finally, it is noted that the development of the effectiveness

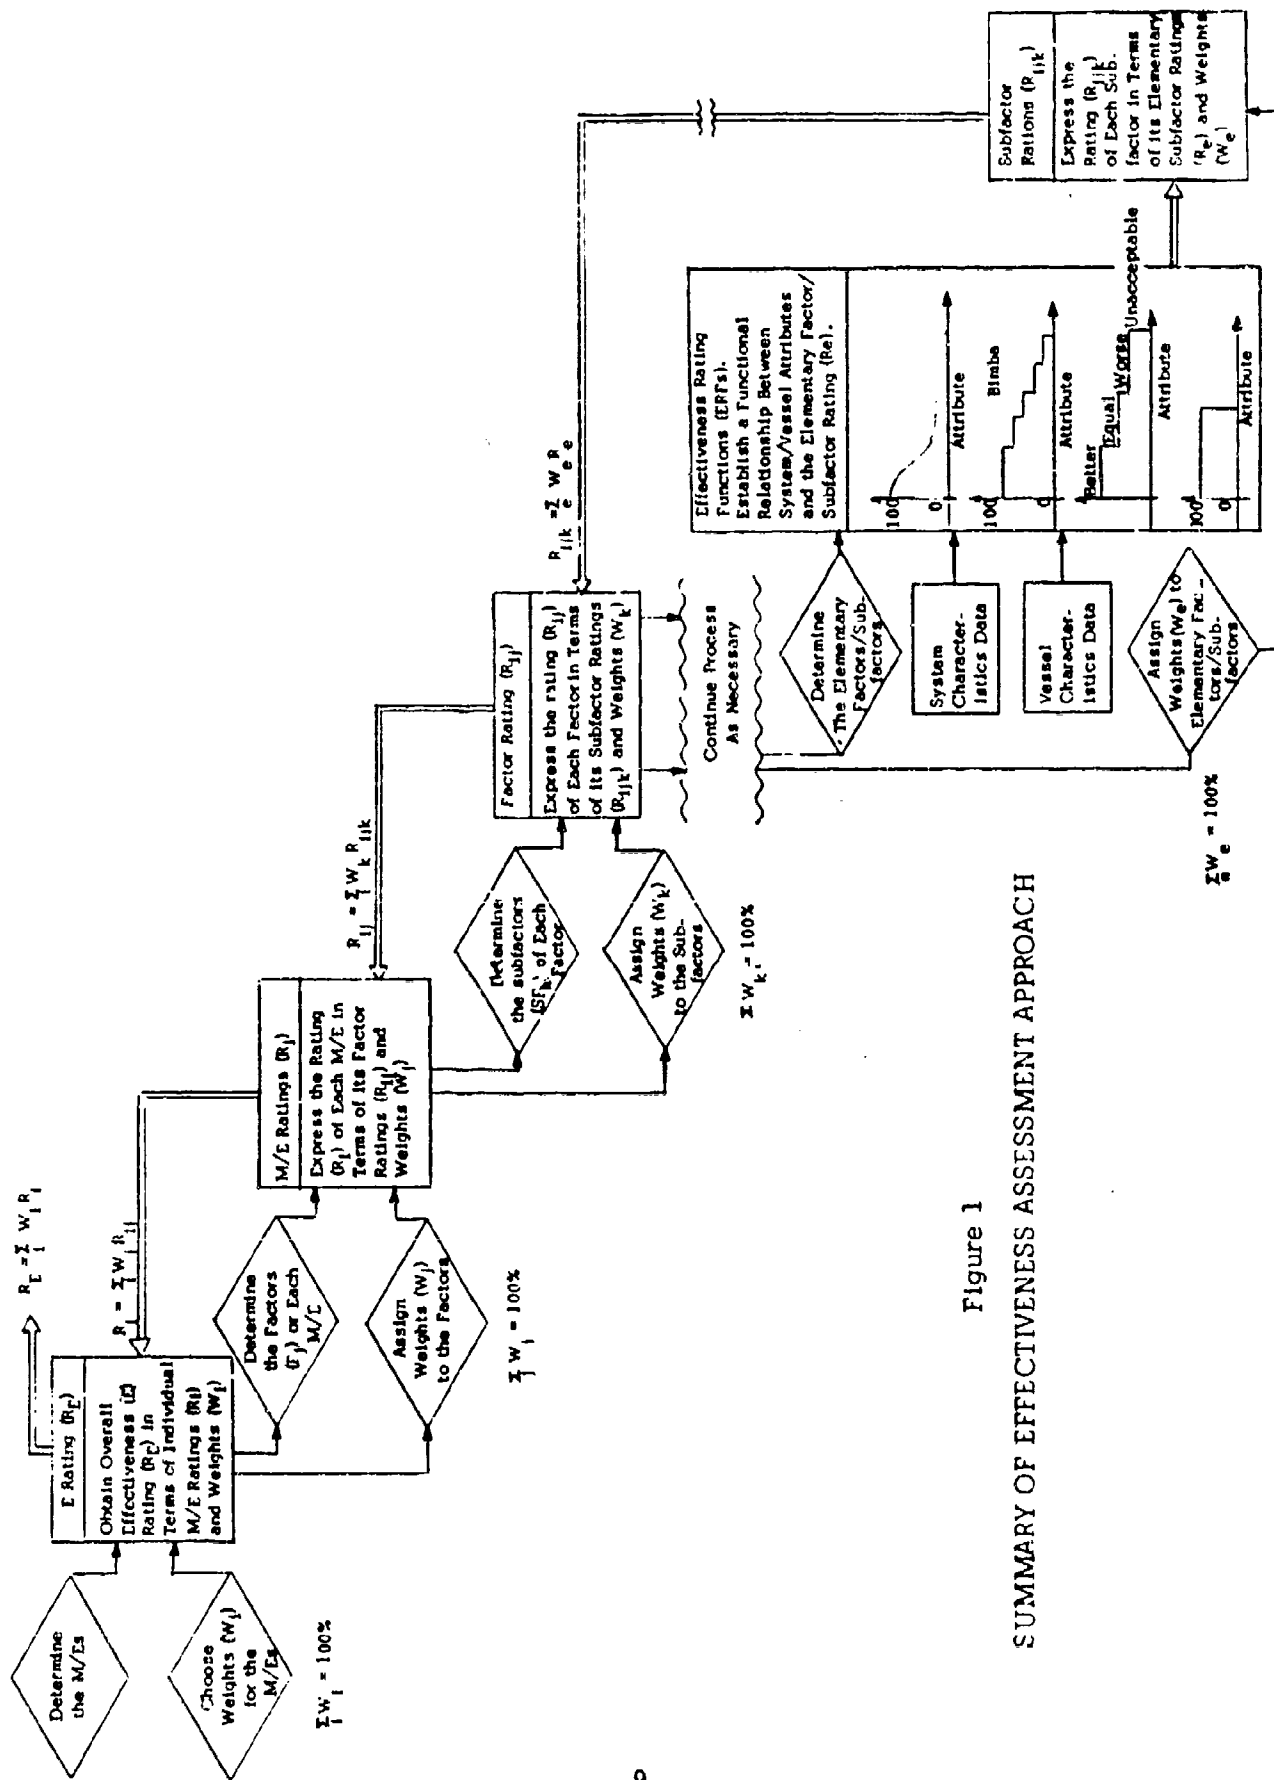

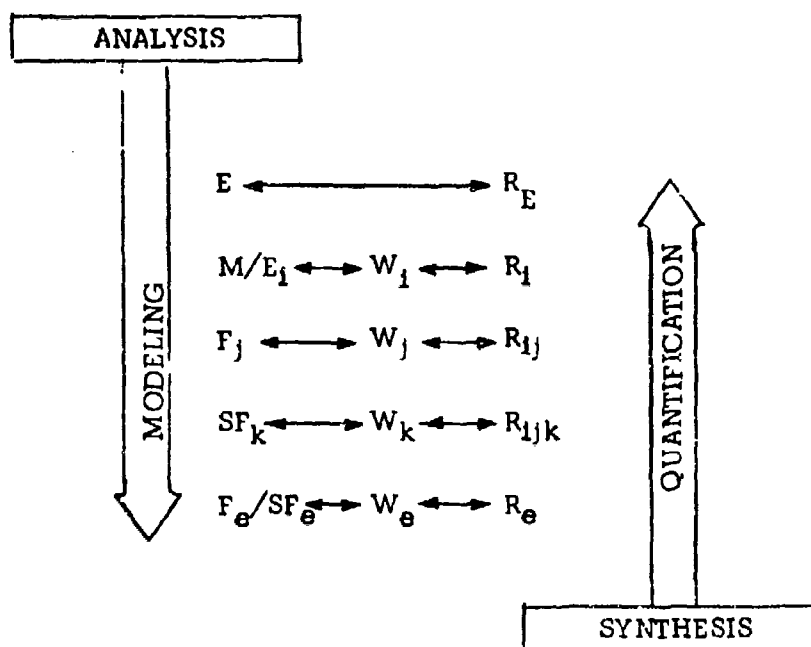

Figure 1
SUMMARY OF EFFECTIVENESS ASSESSMENT APPROACH

model can be characterized as analysis (top to bottom processes), whereas the quantification of effectiveness can be characterized as synthesis (bottom to top process). The above discussed relationships in connection with the effectiveness assessment methodology are summarized below.

Development of the Computer Program for Quantifying Effectiveness

Although the quantification of effectiveness is essentially a straightforward computational procedure, the magnitude of the calculations is such that it is impractical to attempt this manually. As a result, a computer program was developed in order to perform these calculations

rapid and accurately. An important feature of the computer program is that it was not developed for any specific effectiveness model. Instead, the effectiveness model* (and its associated data) is an input to the program. Thus, this computer program is general and applicable to a wide range of problems, and constitutes an essential element of the effectiveness assessment methodology.

Development of the Effectiveness Model

The effectiveness model for the wastewater management system (WMS) candidates and the vessels included in this study was developed in accordance with the principles of the effectiveness assessment methodology, following the prescribed step-by-step procedures (see "Results of Applying the Effectiveness Assessment Methodology to the Candidate System Vessel"). Seven measures of effectiveness (M/Es) were chosen as follows:

- . Adaptability for shipboard installation
- . Performance
- . Operability
- . Personnel Safety
- . Habitability
- . Reliability
- . Maintainability

Each M/E was then broken down into its constituent factors and subfactors. Weights were then assigned to the M/Es and to the factors and subfactors at each level of subordination.

*It is noted that for purposes of the computer program, the effectiveness model does not include the ERFs and the input data include the elementary factor/subfactor ratings for each candidate system/vessel combination.

An effectiveness rating function (ERF) was then developed for each elementary factor/subfactor. Figure 2 shows the form used for documenting these ERFs. This form also facilitates recording the effectiveness attribute data and effectiveness ratings for each viable candidate system/vessel combination associated with the given ERF. The effectiveness model used resulted in 111 individual ERFs which are uniquely identified by the numbering scheme for factors and subfactors. Thus, each viable candidate system/vessel combination is evaluated on the basis of 111 individual criteria.

Decision-Maker Participation

One of the tenets of this effectiveness assessment methodology is that in order to produce meaningful results, it is necessary for the decision-maker to participate in the development of the effectiveness model. In conformity with this principle, the effectiveness model was developed in consultation with, and the active participation of, cognizant U.S. Coast Guard technical representatives. Such Coast Guard participation was extensive in the development of the structure of the effectiveness model, i.e., the choice of the M/Es and the breakdown of each M/E into its factors/subfactors and the associated levels of subordination. The M/E as well as the factor/subfactor weights assignments were made by the Coast Guard. Finally, the development of the ERFs was carefully coordinated with the Coast Guard technical monitor.

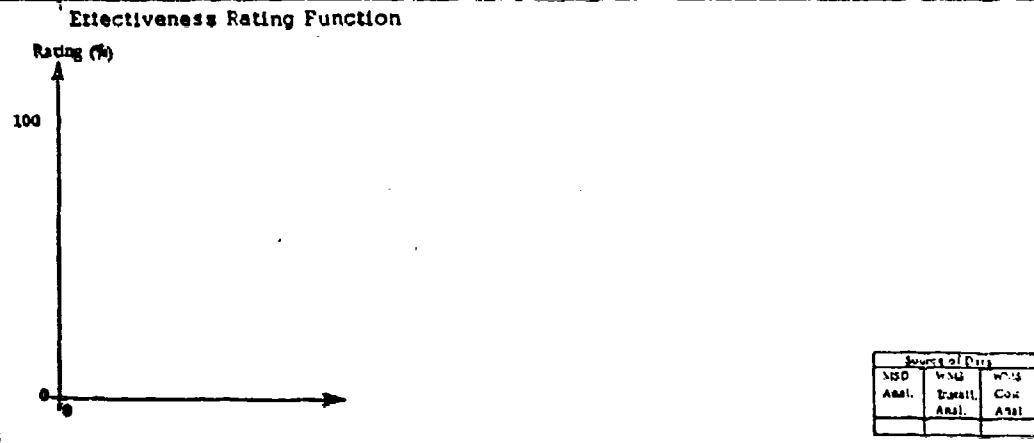

Development and Documentation of Effectiveness Attribute Data

The effectiveness Attribute Data required as input to the effectiveness model is defined by the ERFs. These data came from three different sources which represent three types of analyses performed as part of this study, namely:

EFFECTIVENESS RATINGS FOR ELEMENTARY FACTORS/SUBFACTORS

Attribute Data Rating N/A - Not a viable system/vessel combination

Figure 2
FORM USED FOR DOCUMENTING EFFECTIVENESS RATING
FUNCTIONS AND ASSOCIATED ATTRIBUTE DATA AND RATINGS

- . The MSD analysis
- . The WMS installation analysis
- . The WMS life-cycle cost analysis

Results of the MSD analysis are presented in Volume V of this report. Figure 3 shows a sample form which was used to document MSD related effectiveness attribute data. It is noted from Figure 3 that the MSD effectiveness attribute data was developed and presented on a subsystem level in accordance with the manner in which the MSDs were hybridized to form the candidate WMS concepts. For ease of reference, each MSD subsystem characteristic is keyed to the associated ERF by the unique factor/subfactor identification scheme.

Results of the WMS installation analysis are presented in Volume III of this report. Figure 4 shows a sample form which was used to document WMS installation related effectiveness attribute data. These data were developed and are presented on an overall WMS basis. It is noted from Figure 4 that each WMS installation characteristic is keyed to the associated ERF by the numbering scheme for uniquely identifying each factor and subfactor.

Results of the WMS life-cycle cost analysis are presented in Volume I of this report. Some of the data resulting from this analysis (e.g., vessel resource usage, labor and parts requirements for operation and maintenance), constitute effectiveness attribute data. Most of these data were developed and presented on an overall WMS basis.

The manner in which the above discussed effectiveness attribute data is used for rating elementary factors/subfactors is documented by the corresponding ERFs. In order to facilitate the quantification of effectiveness, the effectiveness attribute data for each viable candidate system/vessel combination was recorded on the form in Figure 2 in the format specified by the ERF. As noted from Figure 2, this form has a provision for indicating the source of the data and it also lists the non-viable system/vessel combinations for which no effectiveness attribute data (and no ratings) were developed.

MSD EFFECTIVENESS ATTRIBUTE DATA

M/E II - PERFORMANCE

MSD _____

Sheet 1 of 4

M/E Factor/ Subfactor Ident. No.	PERFORMANCE Characteristics	Attribute Data	
		Collect. /Transp. Subsystem	Treat. /Disposal Subsystem
311	Effect of peak hydraulic loads in black ⁽¹⁾ water stream on MSD performance ⁽²⁾ (a) No significant effect of black water peaks on MSD subsystem performance. (b) Effect of black water peaks is of short duration, with temporary implications for MSD subsystem performance, easy to overcome. (c) Long-term effect of black water peaks, difficult to overcome, with long-term implications for MSD subsystem performance. (d) No ability of MSD subsystem to handle black water peaks.		
312	Effect of peak hydraulic loads in gray ⁽¹⁾ water stream on MSD performance ⁽²⁾ (a) No significant effect of gray water peaks on MSD subsystem performance. (b) Effect of gray water peaks is of short duration, with temporary implications for MSD subsystem performance, easy to overcome. (c) Long-term effect of gray water peaks, difficult to overcome with long-term implications for MSD subsystem performance. (d) No ability of MSD subsystem to handle gray water peaks.		
321	Effect of low flow conditions/long idle times in black water stream on MSD performance ⁽³⁾ (a) No significant effect of black water low flow conditions/long idle times on MSD subsystem performance. (b) Effect of black water low flow conditions/long idle times of short duration, with temporary implications for MSD subsystem performance, easy to overcome. (c) Long-term effect of black water low flow conditions/long idle times, difficult to overcome, with long-term implications for MSD subsystem performance. (d) No ability of MSD subsystem to handle black water low flow conditions/long idle times.		

(1) Includes instantaneous, hourly and daily loads.
 (2) Peak load handling ability depends on C/T subsystem. The ability of an MSD which employs an influent surge tank to handle peaks usually depends almost entirely on the sizing of this tank.
 (3) An example of low flow condition is when 75% of the crew is not on board vessel for a week and usage rate by remaining 25% of crew is normal. Long idle times are on the order of several weeks of virtually no usage of MSD.

Figure 4
SAMPLE FORM USED FOR DOCUMENTING WMS
INSTALLATION EFFECTIVENESS ATTRIBUTE DATA

Some ERFs call for effectiveness attribute data from more than one source, e.g., some elementary factor/subfactor ratings for the M/Es PERSONNEL SAFETY and for HABITABILITY depend on data from both MSD related as well as WMS installation related effectiveness attribute data. In such cases, both sources of data would be indicated on the form in Figure 2. As was noted earlier, MSD related effectiveness attribute data were developed and documented on a subsystem level. Usually, such MSD data are recorded on the form in Figure 2 for the three major subsystems of each WMS concept, namely:

- The black water Collection/Transport subsystem
- The black water Treatment/Disposal subsystem
- The gray water Treatment/Disposal subsystem

The relationship between the above WMS subsystems and corresponding MSD subsystems is conveyed by Tables 1 and 2. These tables serve as a guide to the MSD effectiveness attribute data presented in Volume V of this report. Table 1 enables easy identification of the MSD subsystems corresponding to each WMS concept. Table 2 facilitates easy identification of each WMS concept which utilizes a given MSD subsystem. Thus, if the data for any given MSD subsystem were changed, Table 2 facilitates easy identification of all WMS concepts that would be affected by such a change.

Quantification of Effectiveness

As a first step in the quantification of effectiveness, a rating was obtained for each viable candidate system/vessel combination with respect to each elementary factor/subfactor. This was accomplished by performing the necessary manipulations of the effectiveness attribute data as specified by the attribute variable of each ERF and then using the quantified attribute variable in the functional relationship specified by the ERF. The resulting ratings were recorded on the form shown in Figure 2. These ratings for the elementary factors/subfactors were then used (together with the effectiveness model) to prepare the necessary inputs for the computer program for quantifying effectiveness. The output from the computer program are overall effectiveness ratings as well as ratings with respect to each M/E for each viable system/vessel combination.

DEFINITIONS

The definitions of certain terms used in conjunction with this effectiveness assessment methodology are given below.

Attribute

A quantitative or qualitative characteristic of the candidate systems/subsystems/equipments and/or vessels which is used as the basis for assigning an effectiveness rating to elementary factors/subfactors. Attribute is also used in connection with the following:

- Attribute Data

The quantitative or qualitative "values" of specific attributes or attribute variables for the candidate system/vessel combinations.

- Attribute Variable

A variable which is used for quantifying an attribute of candidate system/vessel combinations. Attribute variables are often functions which relate attribute data at the system/subsystem/equipment/vessel level to a numerical or qualitative "value" which is used in conjunction with effectiveness rating functions to obtain an effectiveness rating for elementary factors/subfactors.

Effectiveness

The overall quality of a candidate determined on the basis of how well the candidate fulfills specified objectives, requirements and constraints. Effectiveness can be quantified and the resulting number is the effectiveness rating of the candidate which is a quantitative measure of the degree to which the candidate has satisfied the aggregate of all established individual criteria and their relative importance.

Elementary Factor/Subfactor

A factor or subfactor which has no subordinate subfactors and which can be readily related to a single attribute (or a function of one or more attributes) of the candidate system/vessel combinations being analyzed.

Factors

The set of criteria which are implied by a M/E. Factors are characterized (for any candidate system/vessel combination) numerically by two quantities, namely, a rating (which measures how well the candidate satisfies the criterion) and a weight (which indicates how important this factor is in relation to the other factors of the same M/E).

Level of Subordination

The indenture of a given factor or subfactor in the hierarchical structure of the effectiveness model. A numbering scheme used to uniquely identify each factor/subfactor within each M/E indicates the level of subordination.

Measures of Effectiveness (M/Es)

The set of highest level criteria used as the basis for assessing the overall effectiveness of candidate system/vessel combinations. M/Es are characterized (for any candidate system/vessel combination) numerically by two quantities, namely, a rating (which measures how well the candidate satisfies the criterion) and a weight (which indicates how important this M/E is in relation to the others).

Rating

A quantity which measures the degree to which a candidate satisfies either a single criterion or the aggregate of a set of criteria and their relative importance. A rating is given as a percentage in the range of 0 to 100%, using the convention that the higher the rating the greater the degree of acceptability

or quality of the candidate and vice versa. Ratings are used in conjunction with the following:

- . Overall effectiveness
- . M/Es
- . Factors
- . Subfactors
- . Elementary factors/subfactors

Subfactors

The set of criteria which are implied by a factor or another higher level subfactor. Subfactors are characterized (for any given candidate system/vessel combination) numerically by two quantities, namely a rating (which measures how well the candidate satisfies the criterion) and a weight (which indicates how important this subfactor is in relation to the other subfactors at the same level of subordination under the corresponding factor/subfactor).

Weight

A quantity which indicates the importance of each criterion in relation to the others, at the same level of subordination in the hierarchical structure of the effectiveness model. A weight is given as a percentage in the range of 0 to 100%, using the convention that the higher the weight the more important the criterion (in relation to the others at the same level) and vice versa. Weights are assigned such that their sum is equal to 100 for all criteria at the same (and every) level of subordination. Weights are used in conjunction with the following:

- . M/Es
- . Factors
- . Subfactors
- . Elementary factors/subfactors

RESULTS OF APPLYING THE EFFECTIVENESS ASSESSMENT METHODOLOGY TO THE CANDIDATE SYSTEM/VESSEL COMBINATIONS

This section of the report contains the results of applying the effectiveness assessment methodology to the viable candidate system vessel combinations included in this study. The candidate systems are intended for managing both the black (output of commodes, urinals and garbage grinder) and the gray (galley and turbid, i.e., output of sinks, showers, laundry, deck drains, etc.) wastewaters aboard the candidate vessels. The candidate systems consist of the 18 wastewater management system (WMS) concepts in configurations suitable for the vessels included in this study (see Volume IV). Of these potential candidate system/vessel combinations only those considered to be viable candidates on the basis of the installation analysis (see Volume III) were included in the effectiveness analysis.

The results of this analysis include the following:

- . The structure of the effectiveness model which consists of the measures of effectiveness (M/Es) and the factor/subfactors of each M/E together with their associated levels of subordination.
- . Weights for the M/Es and for the factors/subfactors of each M/E at every level of subordination.
- . Elementary factor/subfactor ratings for every viable candidate system/vessel combination. These ratings include the following information:

- .. An effectiveness rating function (ERF) for each elementary factor/subfactor identified by the unique numbering system.
- .. Effectiveness attribute data for each viable candidate system/vessel combination in a format specified by the the ERF.
- .. Elementary factor/subfactor ratings for each viable candidate system/vessel combination.
- . Overall effectiveness ratings as well as ratings with respect to each M/E for all viable candidate system/vessel combinations.

The results of the effectiveness analysis are given in the order indicated above except for the last item. These ratings appear both in the "Summary of Candidate System/Vessel Effectiveness Assessments" in the front of this report as well as in the discussion of the computer program for quantifying effectiveness as the "Output Report" portion of the sample problem.

STRUCTURE OF THE EFFECTIVENESS MODEL

MEASURES OF EFFECTIVENESS (M/Es)	
I -	ADAPTABILITY FOR SHIPBOARD INSTALLATION (Suitability for vessel, ease of installing, effects on vessel)
II -	PERFORMANCE (How well system accomplishes intended functions)
III -	OPERABILITY (Ease of operation, burden on crew, operational expendables)
IV -	PERSONNEL SAFETY (Likelihood, severity and ease of correcting hazards)
V -	HABITABILITY (Noise, odor, heat, user comfort, aesthetics)
VI -	RELIABILITY (Potential for failure free operation)
VII -	MAINTAINABILITY (Ease of correcting failures, manpower and logistic requirements)

Factors/Subfactors

of

I - ADAPTABILITY FOR SHIPBOARD INSTALLATION

Ident.

- 1 • WMS suitability for vessel
 - 11 • Required capacity for vessel vs. actual capacity of system(s)
 - 111 ••• Black
 - 112 ••• Gray
 - 12 •• Materials disallowed or not recommended (as specified in sub-chapter J&F of the Merchant Marine Code and CG MSD regulations)
 - 13 •• Extent of additional support systems/equipment required to accommodate WMS (Compressor, fire fighting equipment, bilge alarm, ozone detector, vents, etc.)
- 2 Ease of WMS installation
 - 21 •• Extent of fixture modifications (i.e., existing commodes/urinals/fixtures vs. special commodes/urinals/fixtures, including hook-up requirements)
 - 22 •• Extent of flush medium supply modifications (existing sea water or fresh water, conversion to fresh or sea water, conversion to non-aqueous medium)
 - 23 •• Ease of installing wastewater Collection/Transport subsystem (Note VCT for JERED and M/T pumps for GATX)
 - 231 ••• Hook-up requirements (e.g., drain piping, electric cables connecting commode, pump and control panel in GATX, but not in JERED)
 - 232 ••• Routing flexibility for drain piping modifications (e.g., continuous slope and vent requirements for conventional full flush drains vs. JERED and GATX drains)
 - 233 ••• Space requirements
 - 234 ••• Modularity of systems (i.e., single package unit vs. decentralization of components)
 - 235 ••• Vent requirements
 - 24 •• Ease of installing waste Treatment/Disposal subsystem
 - 241 ••• Space requirements
 - 242 ••• Hook-up requirements (piping for fuel oil, fresh water, cooling water, compressed air, interconnecting remotely located equipment, overboard discharge line, etc.; electric cables for power supply, remote control panels, etc.; ducting for ventilation, etc.)

- 243 ●●●Modularity of system (single package unit vs. decentralization of components; note that decentralization of components may require additional hook-ups and piping runs).
- 244 ●●● Vent requirements
- 245 ●●● Exhaust stack requirements
- 25 ●● Ease of installing WMS support equipment (e.g., compressor, fire fighting, bilge alarm, ozone detector, vents)
- 26 ●● Ease of compensating for added weight of WMS
- 27 ●● Degree of vessel alterations required for WMS installation
- 271 ●●● SHIPALTS - permanent modifications (e.g., foundations, enlarged doors/hatches, increased capacity requirements for air compressor)
- 272 ●●● Temporary modifications (e.g., cutting access openings)
- 3 ● Effects of WMS on vessel
- 31 ●● Stability
- 32 ●● Trim and list
- 33 ●● Normal range
- 34 ●● Degree of space trade-off/reallocation required
- 35 ●● Vessel resource consumption
- 351 ●●● Electric power
- 352 ●●● Fuel oil
- 353 ●●● Potable water
- 354 ●●● Compressed air
- 355 ●●● Cooling water

Factors/Subfactors

of

II - PERFORMANCE

Ident.

- 1 • WMS figures of merit
 - 11 •• Per capita energy consumption (electric power; power for ventilation, compressed air, pumping flush medium and cooling water; fuel; fuel for fresh water generated aboard vessel).
 - 12 •• Per capita system weight (wet)
 - 13 •• Per capita system volume
- 2 • Adequacy of WMS holding times
 - 21 •• Black
 - 22 •• Gray
- 3 • Ability of WMS to handle, and effects on performance, of abnormal hydraulic loads
 - 31 •• Effect of peak loads
 - 311 ••• Black
 - 312 ••• Gray
 - 32 •• Effect of low flow conditions and/or long idle items
 - 321 ••• Black
 - 322 ••• Gray
 - 33 •• Ability to handle additional personnel
 - 331 ••• Black
 - 332 ••• Gray
- 4 • WMS designed to operate for sustained time periods (e.g., CHT has limited holding capacity vs. JERED, with incinerator, has indefinite capacity)
 - 41 •• Black
 - 42 •• Gray
- 5 • Ability of WMS to handle ground garbage and extraneous materials in black water stream
 - 51 •• Ground garbage
 - 52 •• Foreign materials/objects
 - 53 •• Detergents/surfactants
 - 54 •• Toxic materials (as it affects performance of biological system)
- 6 • Ability of WMS secondary emissions to meet applicable standards
 - 61 •• Discharge of significant air pollutants
 - 62 •• Disposal of oil contaminated residues at sea
- 7 • Performance risk for WMS configuration (i.e., hybrid systems, experience)
 - 71 •• Black
 - 72 •• Gray

Factors/Subfactors

of

III - OPERABILITY

Ident

- 1 • Ease of WMS operation
 - 11 •• Automatic/semi-automatic/manual operation
 - 12 •• Disposal of residue(s)
 - 13 •• Mode changeovers
(primary to overboard discharge cycle/pierside to primary cycle)
 - 14 •• Likelihood of violating effluent standards because of procedural errors
(discharge of effluent which doesn't meet emission standards, flush oil, evaporator residue, wastewater or sludge from holding tank, stack emissions from incinerator which do not meet standards, etc.)
- 2 • Burden of WMS on crew's operating personnel
 - 21 •• Frequency of operator involvement
 - 22 •• Man-hour requirements
 - 23 •• Skill level requirements
 - 24 •• Training requirements
 - 25 •• Effect on work routines/schedules
 - 26 •• Additional personnel (billets) required
- 3 • Operational supplies and support equipment operating requirements for WMS
 - 31 •• Amount of consumables/expendables
 - 32 •• Availability of required specialized or unique consumables/expendables
(i.e., vessel inventory, general commercial availability, federal stock system)
 - 33 •• Operating requirements for special or unique WMS support equipment

Factors/Subfactors
of
IV - PERSONNEL SAFETY

Ident.

- 1 • Contact with/spillage of toxic/dangerous substance associated with WMS
- 11 •• Inherent design feature
- 12 •• Procedural errors/equipment failures (note repair induced hazards)
- 2 • Explosive potential for operator/maintainer of WMS
(e.g., pressurized vessels, vapors)
- 21 •• Inherent design feature
- 22 •• Procedural errors/equipment failures
- 3 • Fire ignition potential of WMS
- 31 •• Inherent design feature
- 32 •• Procedural errors/equipment failures
- 4 • Electric shock potential to operator/maintainer of WMS
- 5 • Physical hazards associated with WMS
- 51 •• Sharp edges
- 52 •• Hot surfaces
- 53 •• Rotating machinery for maintainer

Factors/Subfactors

of

V - HABITABILITY

Ident.

- 1 • Bacterial contamination associated with WMS (user psychological reaction)
- 11 •• Inherent design feature
- 12 •• Procedural errors/equipment failures
- 2 • Fixture efficacy of WMS
- 21 •• Comfort
- 22 •• Flushing procedure requirements
- 23 •• Waste retention in bowl
- 24 •• Likelihood of user contact with flushing medium
- 25 •• Flushing medium appearance
- 26 •• Flushing noise
- 3 • Odors produced by WMS
- 31 •• Inherent design feature
- 32 •• Procedural errors/equipment failures
- 4 • WMS heat generation for operator/maintainer/adjacent berthing and working areas
- 41 •• Inherent design feature
- 42 •• Procedural errors/equipment failures
- 5 • Noise levels in vicinity of WMS for operator/maintainer/adjacent berthing and working areas
- 6 • Vibration produced by WMS for operator/maintainer/adjacent berthing and working areas
- 7 • Effect of WMS on user housekeeping routines

Factors/Subfactors

of

VI - RELIABILITY

Ident.

- 1 • Failure frequency index for WMS
- 2 • Reliability index for WMS (system design/configuration)
 - 21 •• System complexity
 - 22 •• Extent of configuration redundancy
(e.g., additional head spaces/fixtures throughout vessel)
 - 23 •• Extent of equipment/component redundancy
 - 24 •• Degree of equipment failure independence
(i.e., failure of one item will not cause another item to fail)
 - 25 •• Adequacy of equipment ratings
 - 26 •• Provisions for fault actuated cut-off mechanisms to protect system
(i.e., provision for fail safe operation)
- 3 • Reliability risk for WMS
(e.g., hybrid configuration, innovative design, experience)

Factors/Subfactors
of
VII - MAINTAINABILITY

Ident.

- 1 • Corrective Maintenance (CM) requirements for WMS
 - 11 •• Frequency of CM actions (failure frequency)
 - 12 •• Man-hour and skill level requirements
 - 13 •• Ease of repair/replace
 - 131 ••• Accessibility of replaceable components
 - 132 ••• Extent of system modularization
 - 133 ••• Degree of repairability on board vessel (repair vs. replace)
 - 134 ••• Availability of manufacturer field support and training programs
 - 14 •• Spares stockage requirements
 - 141 ••• Extent of spares stockage requirements
 - 142 ••• Special/proprietary items vs. standard supply parts
- 2 • Preventive Maintenance (PM) requirements for WMS
 - 21 •• Frequency of PM actions
 - 22 •• Man-hour requirements
 - 23 •• Effect on watchstander routines
- 3 • Overhaul Maintenance requirements for WMS
 - 31 •• Frequency of overhauls
 - 32 •• Man-hour and skill level requirements
 - 33 •• Special docking requirements
- 4 • Logistic requirements for WMS

1	Corrective Maintenance (CM) requirements for WMS	40					
11	.. Frequency of CM actions (failure frequency)	35					
12	.. Man-hour and skill level requirements	25					
13	.. Ease of repair/replace	25					
131	... Accessibility of replaceable components	40					
132	... Extent of system modularization	20					
133	... Degree of repairability on board vessel (repair vs. replace)	30					
134	... Availability of manufacturer field support and training programs	10					
14	.. Spares stockage requirements	15					
141	... Extent of spares stockage requirements	60					
142	... Special/proprietary items vs. standard supply parts	40					
2	Preventive Maintenance (PM) requirements for WMS	25					
21	.. Frequency of PM actions	35					
22	.. Man-hour requirements	45					
23	.. Effect on watchstander routines	20					
3	Overhaul Maintenance requirements for WMS	20					
31	.. Frequency of overhauls	40					
32	.. Man-hour and skill level requirements	40					
33	.. Special docking requirements	20					
4	Logistic requirements for WMS	15					

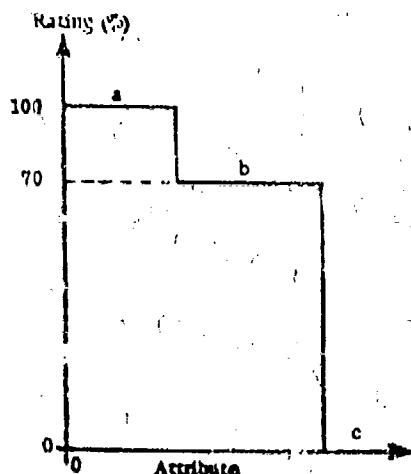

EFFECTIVENESS RATINGS FOR ELEMENTARY FACTORS/SUBFACTORS

M/E

I - ADAPABILITY FOR SHIPBOARD INSTALLATION

111 Required black water handling capacity for vessel vs. actual capacity of WMS

Effectiveness Rating Function

- (a) Actual capacity of WMS equals or exceeds required capacity for vessel.
- (b) WMS marginally suitable for vessel (has 95-99% of required capacity).
- (c) WMS capacity insufficient for vessel (less than 95% of required capacity).

M/E I - ADAPABILITY FOR SHIPBOARD INSTALLATION

13 Extent of additional support systems or equipment required to accommodate WMS

Effectiveness Rating Function

- (a) No additional support systems or equipments required.
- (b) Some additional support systems or equipments required. *
- (c) Many additional support systems or equipments required. **

Examples:

- Firefighting system must be installed with incinerator.
- Bilge alarm required if large tank is installed above bilge.
- Compressor required on vessels that do not already have one.
- Detectors of toxic or noxious gases should be installed with any system that, as an inherent design feature, uses such gases in processing wastes.

* Need for support system/equipment does not significantly reduce WMS suitability for on-board installation.

** Suitability on WMS for installation on vessel is significantly reduced.

EFFECTIVENESS RATINGS FOR ELEMENTARY FACTORS/SUBFACTORS

M/E

I - ADAPABILITY FOR SHIPBOARD INSTALLATION

22

Extent of flush medium supply modifications required for WMS installation

Effectiveness Rating Function

- (a) Existing flush medium is used.
- (b) WMS requires conversion of flush medium to potable water.
- (c) WMS requires conversion of flush medium to recirculating non-aqueous medium.
- (d) WMS requires conversion of flush medium to salt water. *

* Conversion to salt water requires pump re-sizing, tapping into the sea-chest and provision for its corrosive properties. For the PAMLICO, salt water would be used if the drain system were converted to a standard flush system (C.G. supplied information).

EFFECTIVENESS RATINGS FOR ELEMENTARY FACTORS/SUBFACTORS

M/E I - ADAPABILITY FOR SHIPBOARD INSTALLATION

231 Hookup requirements* for WMS Collection/Transport subsystem installation

Effectiveness Rating Function (a) No additional hookup requirements beyond existing ones.

- (b) Requires piping for recirculation of flush medium (in existing gravity drain system).
- (c) Special and centralized Collection/Transport subsystem required.
- (d) Special and non-centralized Collection/Transport subsystem required (includes conversion from reduced flush vacuum collection to a standard gravity drain system, with or without recirculation).

NOTE: If the WMS is an MSD being installed on a vessel with a standard drain system and no existing WMS, the following ratings would apply to the basic MSDs considered in this study.

100 - CHT, Grumman
90 - Chrysler
40 - JERED
0 - GATX

E.g., drain piping; electric cables connecting commode, M/T pump and control panel in GATX, but not in JERED.

232

Routing flexibility for drain piping modifications* associated with WMS Collection/Transport subsystem installation**

Effectiveness Rating Function

Rating (%)

(a) Routing is highly flexible.

(b) Routing is moderately flexible, with some restrictions.

(c) Routing is highly inflexible.

NOTES: 1. With gravity drainage, lines must always slope downward and require venting.

2. Smaller size lines are inherently more flexible.

3. With the pump or vacuum Collection/Transport subsystem, sharp bends, rises and long runs can be accommodated in piping.

* Of the three relevant categories of routing of lines (piping, ventilation, electrical), piping is the most important for assessing use of WMS installation.

** In all cases, WMS installation is to be considered from the point of view of modifications required to existing conditions.

EFFECTIVENESS RATINGS FOR ELEMENTARY FACTORS/SUBFACTORS

M/E I - ADAPABILITY FOR SHIPBOARD INSTALLATION

234 Modularity of WMS Collection/Transport subsystem (as it affects installation)

Effectiveness Rating Function

- (a) Degree of modularity of subsystem aids in installation of C/T subsystem.
- (b) Degree of modularity of subsystem results in some (minimal) difficulty in installation of C/T subsystem.
- (c) Degree of modularity of subsystem results in moderate difficulty in installation of C/T subsystem.

NOTE: On vessels that do not currently have a WMS, a high degree of modularity aids in installation, and a high degree of subsystem centralization (as in the JERED) results in difficulties for installation.

N/A - Not a viable system/vessel combination

EFFECTIVENESS RATINGS FOR ELEMENTARY FACTORS/SUBFACTORS

M/E I - ADAPABILITY FOR SHIPBOARD INSTALLATION

241 Space requirements for WMS waste Treatment/Disposal subsystem installation

Effectiveness Rating Function

- (a) Volume required is minimal and dimensions of equipment present no problems in fitting equipment into available compartment space.
- (b) Volume required is moderate and dimensions of equipment present no problems in fitting equipment into available compartment space.
- (c) Volume required is moderate and dimensions equipment do present a problem in fitting equipment into available compartment space.
- (d) Large volume required and dimensions of equipment do present a problem in fitting equipment into available compartment space.

* The two main factors are (i) deck area required and (ii) height required.

NOTE: Volumes are calculated as follows:

- (1) Fixture volumes are calculated using smallest space envelopes.
- (2) Pipe volume is the volume of a square tube with side = outside diameter of pipe.
- (3) Other equipment: deck area: smallest rectangle enclosing all equipment in a single package plus extra dimension area required for operation and maintenance. Height: either maximum height of equipment, or full compartment height, if space above is not usable for any other purposes.

N/A - Not a viable system/vessel combination

EFFECTIVENESS RATINGS FOR ELEMENTARY FACTORS/SUBFACTORS

M/E I - ADAPABILITY FOR SHIPBOARD INSTALLATION

25 Ease of installing WMS support equipment

Effectiveness Rating Function

- (a) No support equipment required.
- (b) Some support equipment required but easy to install
- (c) Much support equipment required and difficult to install

Examples:

- Firefighting system must be installed with incinerator.
- Bilge alarm required if large tank is installed above bilge.
- Compressor required on vessels that do not already have one.
- Detectors of toxic or noxious gases should be installed with any system that, as an inherent design feature, uses such gases in processing wastes.

M/E I - ADAPABILITY FOR SHIPBOARD INSTALLATION

245 Exhaust stack requirements for WMS waste Treatment/Disposal subsystem installation

Effectiveness Rating Function

- (a) Exhaust not required.
- (b) Exhaust required, size of stack relatively small and stack can be run via existing ship's stack enclosure (Ridley).
- (c) Exhaust required, size of stack relatively large and stack can be run via existing ship's stack enclosure.
- (d) Exhaust required, size of stack relatively small and stack cannot be run via existing ship's stack enclosure.
- (e) Exhaust required, size of stack relatively large and stack cannot be run via existing ship's stack enclosure.

NOTES: 1. Electric Incinerator requires small (2") exhaust.
2. Fuel Incinerator requires large (10") exhaust.

Attribute Data

Rating

N/A - Not a viable system/vessel combination

- L - Range limit index due to WMS consumption of fuel and/or fresh water for i^{th} viable candidate WMS on vessel v.
- F - Fuel consumption (gallons) of i^{th} viable candidate WMS on vessel v during maximum holding time period for vessel.
- W - Fresh water consumption (gallons) of i^{th} viable candidate WMS on vessel v during maximum holding time for vessel.
- C_F - Remaining gallons of fuel after maximum holding time.
- C_W - Remaining gallons of fresh water after maximum holding time

Data given in the form:

F, W

VESSEL FUEL OIL AND FRESH WATER CAPACITIES AND CONSUMPTION RATES

Vessel	Required Maximum Holding Time (Hrs)	FRESH WATER				FUEL OIL		
		Capacity (Gals)	Usage Rate (Gals/Day)	Generation Rate (Gals/Day)	Remaining Gallons(7) After Max. Hold. Time	Capacity (Gals)	Usage Rate (Gals/Day)	Remaining Gallons(8) After Max. Hold. Time
Gallatin (378')	97.5	17,794	6,500	7,200	17,794	(2) 215,500	3,000	203,370
Vigorous (210')	172.0	7,700	2,000	2,500	7,700	42,000	1,800	29,094
Firebush (180')	277.9	52,995 ⁽³⁾	2,300	0	26,361 ⁽³⁾	27,875 ⁽³⁾	1,300	12,821
Pamlico (160') New Construction	501.0	19,255 ⁽¹⁾	600	0	6,730 ⁽⁴⁾	6,349	500 ⁽⁵⁾	0 ⁽⁶⁾
White Sage (133')	65.5	10,066	135	0	9,697	12,864	720	10,898
Point Herron (82')	99.0	1,385	150	0	765	2,000	150	1,380

(1) Does Not Include 13,028 Gals of Cargo Water

(2) After ShipAlt Removal of Flume Tank

(3) Firebush supplies Lighthouses with Fresh Water and Fuel as follows:

(a) Ambrose - Quarterly: 20,000 gals water, 10,000 gals fuel oil

(b) Execution Rock - Every 2 months: 1,500 gals water, no fuel oil

(c) Throggs Neck - Every 2 months: 1,200 gals water, 1,200 gals fuel oil

These are taken directly from vessels tanks, there are no separate cargo tanks.

(4) This figure includes water used for flushing since Pamlico is currently outfitted with a Colt Industries Vacuum Collection System - which utilizes fresh water flush.

(5) This figure was obtain by assuming a typical operational profile of 3 days transit out, 3 days on station, 3 days return transit. Transit fuel consumption is assumed to be 600 gallons per day, and on-station 300 gallon per day.

(6) Pamlico fuel capacity is insufficient to sustain ship operation for projected required maximum holding time.

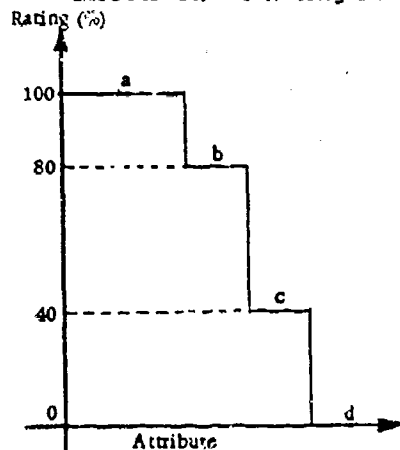

(7) Designated by C_W .

(8) Designated by C_F .

EFFECTIVENESS RATINGS FOR ELEMENTARY FACTORS/SUBFACTORS
M/E I - ADAPABILITY FOR SHIPBOARD INSTALLATION

34 Degree of space trade-off/reallocation required for WMS installation

Effectiveness Rating Function

- (a) No space trade-off/reallocation required.
- (b) Minimal degree of space trade-off/reallocation required.
- (c) Moderate degree of space trade-off/reallocation required.
- (d) High degree of space trade-off/reallocation required.

N/A - Not a viable system/vessel combination

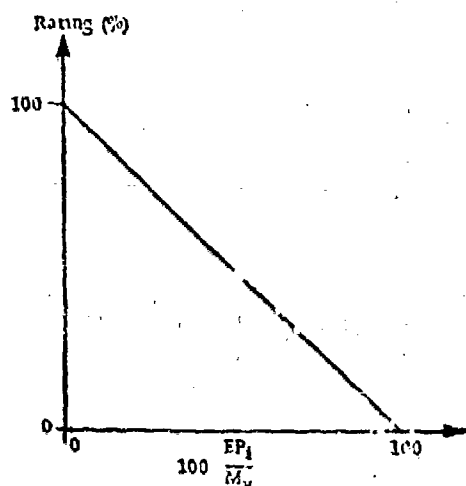

EFFECTIVENESS RATINGS FOR ELEMENTARY FACTORS/SUBFACTORS

M/E II - PERFORMANCE

21 Adequacy of WMS black water holding times

Effectiveness Rating Function

$$R_{iv}(\%) = HT_b \quad 0 \leq HT_b \leq 100$$

$R_{iv}(\%)$ - Rating (%) of i^{th} viable candidate WMS on vessel v
 HT_b - % of required black water holding time met by WMS

Vessel	Maximum Holding Time Required (Hours) *
GALLATIN	97.5
VIGOROUS	172.0
FIREBUSH	277.9
PAMLICO	501.0
WHITE SAGE	65.5
POINT HERRON	99.0

* Based on vessel mission profiles. A WMS which employs an incinerator or evaporator is considered to meet 100% of the required holding time.

The holding time of a WMS which employs a holding tank (for wastewater or sludge) is determined by the ratio of available tank capacity to required capacity.

N/A - Not a viable system/vessel combination

EFFECTIVENESS RATINGS FOR ELEMENTARY FACTORS/SUBFACTORS

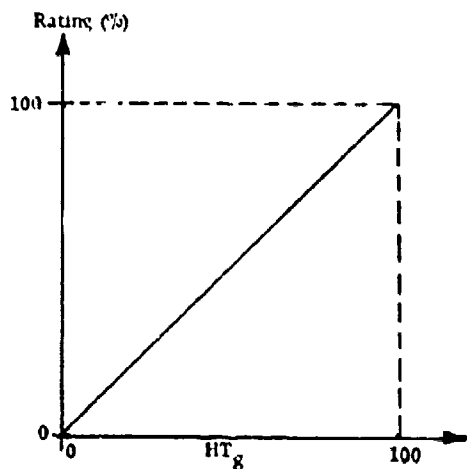

M/E

II - PERFORMANCE

311

Effect of peak hydraulic loads* in black water stream on WMS performance

Effectiveness Rating Function

$R_{iv}(\%) = GIST_b$ - If the WMS black water subsystem has a Grumman MSD, or other MSD requiring an influent surge tank
 = Rating based on $Z_{C/T}$, otherwise

$R_{iv}(\%) = \text{Rating } (\%) \text{ of } i\text{th viable candidate WMS on vessel } v$

* Includes instantaneous, hourly and daily loads.

NOTES: 1. A WMS gets the rating that its black water C/T subsystem would receive
 2. The ability of the Grumman or other MSD requiring an influent surge tank to handle peaks depends almost entirely on the sizing of its influent surge tank; optimum sizing cannot always be provided on all vessels.

Rating

N/A - Not a viable system/vessel combination

80

II - 311

$GIST_b$ - % of required influent surge tank capacity for Grumman (or other MSD requiring an influent surge tank in black water stream) provided by installation.

$Z_{C/T}$ - Peak load handling ability of WMS (black water) C/T subsystem which does not employ an influent surge tank.

Data given in the form:

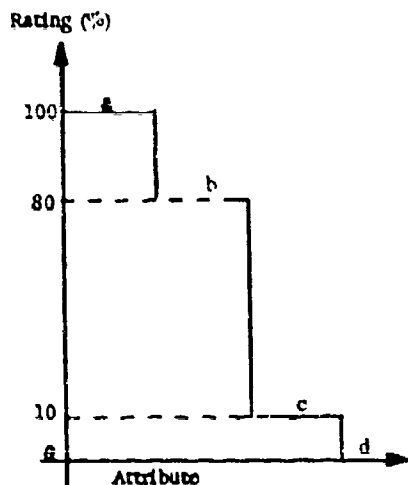

$GIST_b$ - If WMS (black water) C/T subsystem employs an influent surge tank

$Z_{C/T}$ - If WMS (black water) C/T subsystem does not employ an influent surge tank

NOTE: $Z_{C/T}$ is not vessel dependent

$GIST_b$ is vessel dependent

Definition and Corresponding Ratings for $Z_{C/T}$

- (a) No significant effect of black water peaks on WMS subsystem performance.
- (b) Effect of black water peaks is of short duration, with temporary implications for WMS subsystem performance, easy to overcome.
- (c) Long-term effect of black water peaks, difficult to overcome, with long-term implications for WMS subsystem performance.
- (d) No ability of WMS subsystem to handle black water peaks.

EFFECTIVENESS RATINGS FOR ELEMENTARY FACTORS/SUBFACTORS

EFFECTIVENESS RATINGS FOR ELEMENTARY FACTORS/SUBFACTORS

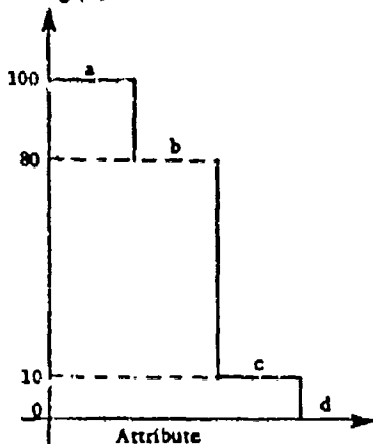

M/E II - PERFORMANCE

331

Ability of black water portion of WMS to handle additional personnel
(on a long-term basis)*

Effectiveness Rating Function

$$R_{WMS} = \min(R_{C/T}, R_{T/D})$$

Rating (%)

R_{WMS} - Rating for WMS

$R_{C/T}$ - Rating for (black water) C/T subsystem

$R_{T/D}$ - Rating for black water T/D subsystem. If this subsystem employs a holding tank it receives its full rating only if 100% of the required tank capacity is met by the installation (i.e., if $HTC_b = 100\%$). Otherwise, its rating is 0.

HTC_b - % of required black water (or sludge) holding tank capacity provided by installation.

(Continued)

* Resulting in a long term increase in average black water stream hydraulic loading. The ability of a WMS which employs a black water (or sludge) holding tank to handle additional personnel may be determined by the size of that tank; optimum sizing cannot always be provided on the vessel.

EFFECTIVENESS RATINGS FOR ELEMENTARY FACTORS/SUBFACTORS

M/E II - PERFORMANCE

51 Ability of WMS to handle ground garbage in black water stream *

Effectiveness Rating Function

Rating (%)

Rating for WMS is based on rating for black water T/D subsystems portion which handles the ground garbage (e.g., incinerator or holding tank).

(a) WMS subsystem will handle ground garbage in black water stream on a long-term basis.

(b) WMS subsystem will handle ground garbage in black water stream on at least at short-term basis.

(c) WMS subsystem will not handle ground garbage in black water stream.

Data is not vessel dependent.

* In some WMS configurations ground garbage bypasses the (sewage) C/T subsystem and instead is routed by a separate line directly into the T/D subsystem (e.g., to holding tank or incinerator).

61 Ability of WMS secondary emissions to meet applicable standards for the discharge of air pollutants

Effectiveness Rating Function

$$R_{WMS} = 100(R_{C/T} \cdot R_{B/T/D} \cdot R_{G/T/D})$$

Rating (%)

R_{WMS} - Rating for WMS

$R_{C/T}$ - Rating for (black water) C/T subsystem

$R_{B/T/D}$ - Rating for black water T/D subsystem

$R_{G/T/D}$ - Rating for gray water T/D subsystem

Data given in the form (not vessel dependent):

$Z_{C/T}$ $Z_{B/T/D}$ $Z_{G/T/D}$ } Attribute
 $R_{C/T}$ $R_{B/T/D}$ $R_{G/T/D}$ } Ratings

Definitions of $Z_{C/T}$, $Z_{B/T/D}$, $Z_{G/T/D}$

- (a) No possibility of discharge of significant air pollutants from WMS subsystem.
- (b) WMS subsystem will meet standards under normal operating conditions and is likely to continue to meet them under unusual operating conditions.
- (c) WMS subsystem will meet standards under normal operating conditions and there is a strong possibility of non-conformance to standards under unusual operating conditions.

III - OPERABILITY

12 Ease of disposal of WMS residue(s)*

Effectiveness Rating Function

$$R_{WMS} = \text{Min}(R_{C/T}, R_{T/D}, R_{G_{T/D}})$$

Rating (%)

R_{WMS} - Rating for WMS

$R_{C/T}$ - Rating for (black water) C/T subsystem

$R_{T/D}$ - Rating for black water T/D subsystem

$R_{G_{T/D}}$ - Rating for gray water T/D subsystem

(Continued)

* Residue is any by-product of normal WMS operation, disposal of which is a regular operating task. Examples are ash produced by an incinerator, seal water used by JERED vacuum pumps, evaporator residue, sludge or wastewater held in a tank, etc.

NOTE: Length of time required for disposal is the main factor in determining the rating; other factors are ease of access to area of WMS containing the residue, amount of residue to be disposed of, and ease of storing residue on board or taking it off vessel, as appropriate.

Attribute Data →

← Rating

N/A - Not a viable system/vessel combination

Definition and Values for L

- (a) No chance (L = 0)
- (b) Highly unlikely (L = 1)
- (c) Fair to even chance (L = 2)
- (d) Highly likely (L = 4)

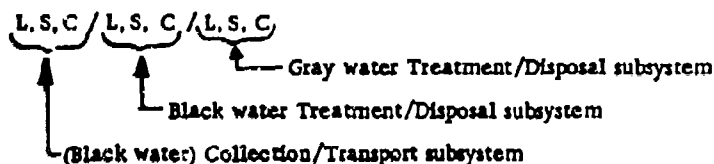

Definition and Values for S

- (a) No resultant injury (S = 1)
- (b) Results in injury of low to moderate severity (requiring first aid or limited medical treatment) (S = 2)
- (c) Results in severe injury or death (S = 4)

Definition and Values for C

- (a) Hazardous situation can be easily corrected (C = 1)
- (b) Hazardous situation is difficult to correct (C = 2)
- (c) Hazardous situation cannot be corrected (C = 4)

WMS data (Independent of vessel) is given in the form:

* Examples:

- Leakage of fumes from incinerator into adjacent berthing and working spaces.
- Hydrogen sulfide (a toxicant) may be generated in sewage holding tanks.
- Fresh water connections to MSD subsystems have a potential for contaminating the vessel's potable water supply with toxic/dangerous substances.
- Sewage contamination.
 - .. The following pathogens may be transmitted through sewage.
 - Tetanus (bacteria)
 - Typhoid (bacteria)
 - Dysentery (bacteria)
 - Cholera (bacteria)
 - Hepatitis (virus)
 - Polio (virus)
 - .. Possible methods of infection (a healthy person may be a carrier; infection hazard depends on a person's resistance).
 - Oral (from hands while smoking or eating) - the most common method of transmitting enteric (intestinal) diseases.
 - Through breaks in skin (cuts, abrasions, sores).
 - Eyes and nose (from hands).

EFFECTIVENESS RATINGS FOR ELEMENTARY FACTORS/SUBFACTORS

IV - PERSONNEL SAFETY

12

Hazard of contact with/spillage of toxic/dangerous substances* due to procedural errors/equipment failures of WMS

Effectiveness Rating Function

Rating (%)

$$HI = HI_{C/T} + HI_{B_{T/D}} + HI_{G_{T/D}}$$

$$HI_{C/T} \cdot HI_{B_{T/D}} \cdot HI_{G_{T/D}} = L \times S \times C$$

R_i (%) = Rating (%) of i^{th} viable candidate WMS (Independent of vessel)

HI - Hazard index of contact with/spillage of toxic/dangerous substances due to procedural error/equipment failures of WMS

$HI_{C/T}$ - Hazard index for (black water) Collection/Transport subsystem

$HI_{B_{T/D}}$ - Hazard index for black water Treatment/Disposal subsystem

$HI_{G_{T/D}}$ - Hazard index for gray water Treatment/Disposal subsystem

L - Likelihood of hazard for C/T and T/D (black or gray) subsystems

S - Severity of hazard for C/T and T/D (black or gray) subsystems

C - Hazard correction for C/T and T/D (black or gray) subsystems

M - Maximum possible value of HI =

$$3(4 \times 4 \times 4) = 192$$

* See Examples and Legend following.

$$R_i (\%) = 100 (1 - HI/48) \quad 0 \leq HI \leq 48$$

$$= 0 \quad 48 < HI \leq 192$$

Effectiveness Rating Function

$$HF = I \times HI$$

$$HI = HI_{C/T} + HI_{T/D} + HI_{T/D}$$

$$HI_{C/T} = \frac{HI}{C/T}, HI_{T/D} = \frac{HI}{T/D}, HI_{T/D} = L \times S \times C$$

 $R_{iv}(\%)$ - Rating (%) of i th viable candidate WMS on vessel v

HF - Hazard factor for fire ignition potential due to procedural errors/equipment failures of WMS

I - Installation index (for personnel safety)

HI - Hazard index for WMS

 $HI_{C/T}$ - Hazard index for (black water) Collection/Transport subsystem $HI_{T/D}$ - Hazard index for black water Treatment/Disposal subsystem $HI_{T/D}$ - Hazard index for gray water Treatment/Disposal subsystem

L - Likelihood of hazard for C/T and T/D (black or gray) subsystems

S - Severity of hazard for C/T and T/D (black

or gray) subsystems

C - Hazard correction for C/T and T/D (black or gray) subsystems

M - Maximum possible value of HF =

4(3) (4 x 4 x 4) = 768 (Continued)

$$R_{iv}(\%) = 100 (1 - HF/48) \quad 0 \leq HF \leq 48$$

$$= 0 \quad 48 < HF \leq 768$$

Attribute Data

Rating

N/A - Not a viable system/vessel combination

132

Definition and Values for I

- (a) Likelihood of hazardous situation is not increased due to location of any portion of WMS ($I = 1$)
- (b) Likelihood of hazardous situation is increased due to proximity of any portion of WMS to working or berthing area ($I = 2$)
- (c) Likelihood of hazardous situation is increased due to proximity of any portion of WMS to fuel storage area ($I = 4$)

Definition and Values for L

- (a) No chance ($L = 0$)
- (b) Highly unlikely ($L = 1$)
- (c) Fair to even chance ($L = 2$)
- (d) Highly likely ($L = 4$)

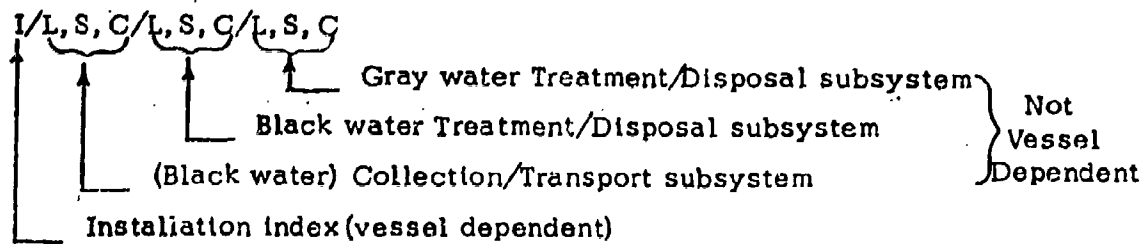

Definition and Values for S

- (a) No resultant injury ($S = 1$)
- (b) Results in injury of low to moderate severity (requiring first aid or limited medical treatment) ($S = 2$)
- (c) Results in severe injury or death ($S = 4$)

Definition and Values for C

- (a) Hazardous situation can be easily corrected ($C = 1$)
- (b) Hazardous situation is difficult to correct ($C = 2$)
- (c) Hazardous situation cannot be corrected ($C = 4$)

WMS/vessel data is given in the form

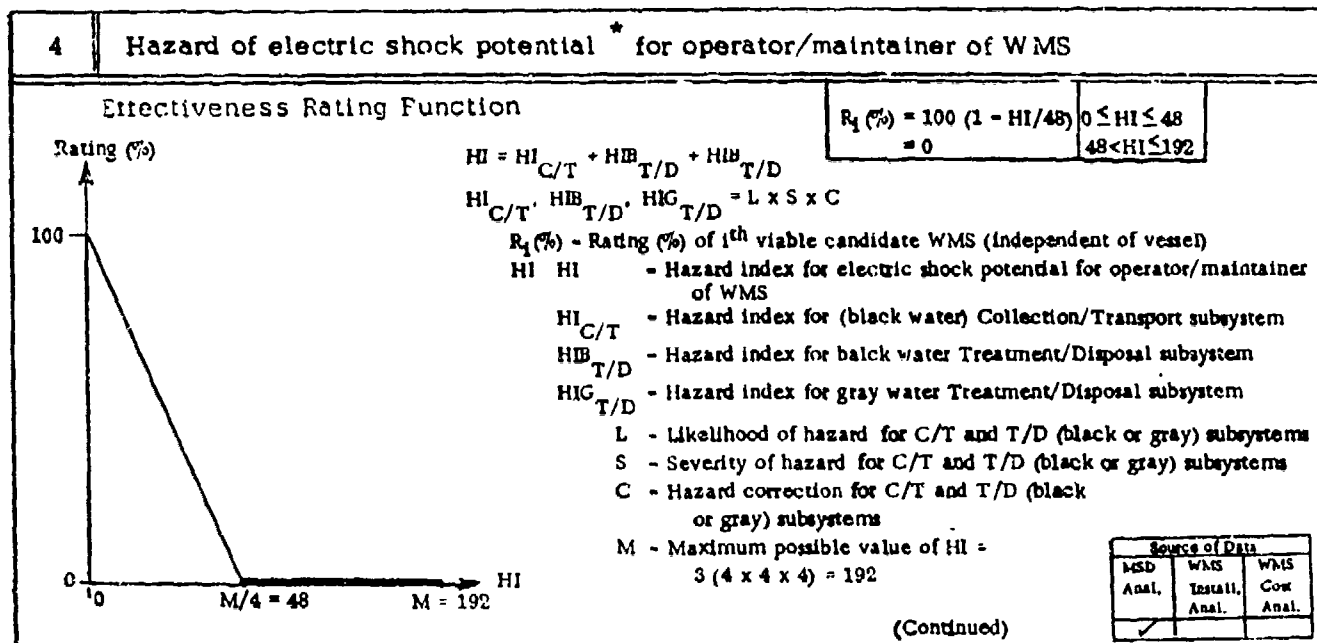

* Oil used for flushing (in Chrysler) is not flammable under ordinary conditions. However, at high temperatures, e.g., in the presence of a fire, it will support combustion.

Attribute Data

Rating

N/A - Not a viable system/vessel combination

143

Data given in the form (not vessel dependent):

Definitions of $Z_{C/T}$, $ZB_{T/D}$, $ZG_{T/D}$

- (a) A bacterial contamination problem due to procedural errors/equipment failures of WMS subsystem is highly unlikely.
- (b) Procedural errors/equipment failures of WMS subsystem are likely to cause a bacterial contamination problem.

NOTE: The JERED MSD, because it has a vacuum collection system, is less likely to expose personnel to sewage in case of a line break; the Chrysler, however, will not only expose personnel to sewage but also to bacteria-contaminated oil; the GATX is more likely to expose personnel to bacterial contamination due to its pressurized sewer lines.

EFFECTIVENESS RATINGS FOR ELEMENTARY FACTORS/SUBFACTORS

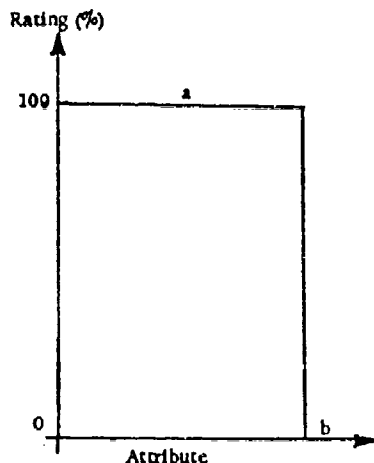

M/E

V - HABITABILITY

21

WMS fixture comfort

Effectiveness Rating Function

(a) Commodes and urinals are comfortable and easy to use, even under ship's motion.

(b) Commodes and urinals are not comfortable and not easy to use under ship's motion.

24 Likelihood of user contact* with WMS fixture flushing medium

Effectiveness Rating Function

Rating (%)

(a) User is unlikely to come into contact with flushing medium.

(b) User is more likely to come into contact with flushing medium than with standard water flushed fixture.

* Due to flushing medium composition or fixture design, motion of vessel (which may cause splatter, splashing, or spillage of flushing medium) WMS concept implementation, equipment failures, or operator errors. Systems which employ a pressurized sewer line (GATX) or oil return line (Chrysler) are more likely to expose personnel to fixture flushing medium or sewage in case of a line break.

Data vessel not dependent.

Attribute Data

Rating

N/A - Not a viable system/vessel combination

Definition and values for I

- (a) Location of WMS is not likely to raise noise level due to proximity to working and berthing areas ($I = 1$)
- (b) Location of WMS is likely to raise noise level due to proximity to working and berthing areas ($I = 2$)

Definition and values for $NI_{C/T}$, $NIB_{T/D}$, $NIG_{T/D}$

- (a) Subsystem is silent or nearby silent ($NI_{C/T}$, $NIB_{T/D}$, $NIG_{T/D} = 1$)
- (b) Noise level of subsystem is approximately equal to background noise level of vessel ($NI_{C/T}$, $NIB_{T/D}$, $NIG_{T/D} = 2$)
- (c) Subsystem is very loud, produces constant noise, drowns out vessel background noise in immediate area of the system; must shout to be heard ($NI_{C/T}$, $NIB_{T/D}$, $NIG_{T/D} = 4$)

WMS/vessel data is given in the form:

EFFECTIVENESS RATINGS FOR ELEMENTARY FACTORS/SUBFACTORS

M/E

V - HABITABILITY

6

Vibration levels for nearby personnel* produced by WMS machinery

Effectiveness Rating Function

Rating (%)

$$VF = 1 \times VI$$

$$VI = VI_{C/T} + VI_{B_{T/D}} + VI_{G_{T/D}}$$

$R_{iv}(\%)$ - Rating (%) of i^{th} viable candidate WMS on vessel v

VF - Vibration factor for nearby personnel due to WMS and installation

I - Installation index (for vibration)

VI - Vibration index for WMS

$VI_{C/T}$ - Vibration index for (black water) Collection/Transport subsystem

$VI_{B_{T/D}}$ - Vibration index for black water Treatment/Disposal subsystem

$VI_{G_{T/D}}$ - Vibration index for gray water Treatment/Disposal subsystem

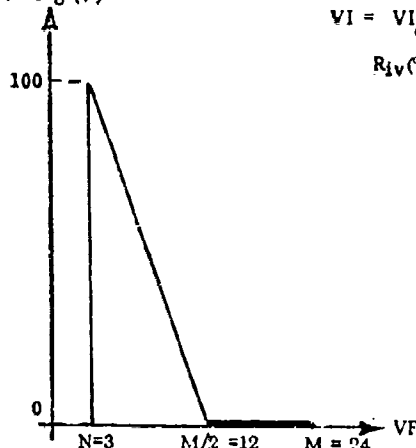

M - Maximum possible value of VF = 2 (4 + 4 + 4) = 24

N - Minimum value of VF = 1(1 + 1 + 1) = 3

* For operator/maintainer/adjacent working and berthing areas.

$$R_{iv}(\%) = 100 - \frac{100}{9} (VF - 3) \quad 3 \leq VF \leq 12$$

$$= 0 \quad 12 < VF \leq 24$$

Rating

N/A - Not a viable system/vessel combination

159

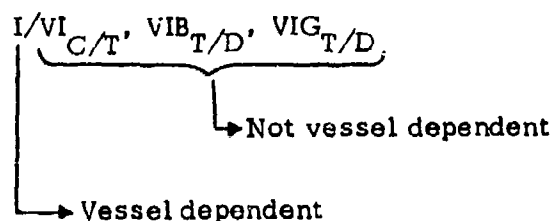

Definition and values for I

- (a) Location of WMS is not likely to raise vibration level due to proximity to working and berthing areas (I = 1)
- (b) Location of WMS is likely to raise vibration level due to proximity to working and berthing areas (I = 2)

Definitions and values for $VI_{C/T}$, $VIB_{T/D}$, $VIG_{T/D}$

- (a) WMS subsystem produces little or no perceptible vibration in addition to background level on vessel ($VI_{C/T}$, $VIB_{T/D}$, $VIG_{T/D} = 1$).
- (b) WMS subsystem produces perceptible vibration, but similar to vessel background ($VI_{C/T}$, $VIB_{T/D}$, $VIG_{T/D} = 2$).
- (c) WMS subsystem produces abnormal & disturbing intensity and/or frequency of vibration ($VI_{C/T}$, $VIB_{T/D}$, $VIG_{T/D} = 4$).

Attribute Data →

← Rating

N/A - Not a viable system/vessel combination

Definitions of $Z_{C/T}$, $ZB_{T/D}$, $ZG_{T/D}$

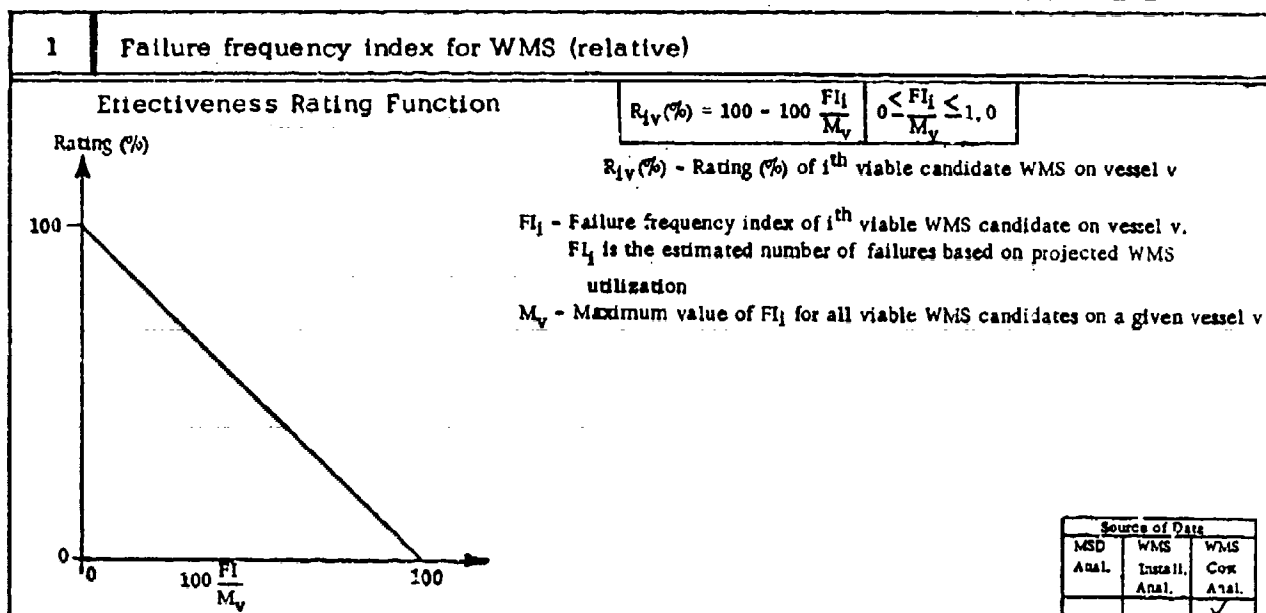

- (a) WMS subsystem characteristics have no effect on user housekeeping routines. Applies to CHT, JERED, and Grumman. (If a very large amount of detergent is deposited in the CHT, some foaming may result.)
- (b) WMS subsystem characteristics have an effect on user housekeeping routines. Applies to the Chrysler and GATX MSDs.

- NOTES:
- 1. Detergent should not be dumped into fixtures associated with the Chrysler C/T and T/D subsystems.
 - 2. Detergent is very likely to cause foaming in evaporator.

Attribute Data

Rating

N/A - Not a viable system/vessel combination

165

Data given in the form:

$$Z_C, Z_T/ZB_{T/D}/ZG_{T/D}$$

Definition and values for $Z_C, Z_T, ZB_{T/D}, ZG_{T/D}$

- (a) There is configuration redundancy, i.e., failure of any one equipment will not result in the failure of the subsystem ($Z_C, Z_T, ZB_{T/D}, ZG_{T/D} = 1$).
- (b) There is no configuration redundancy, i.e., failure of one equipment will result in the failure of the subsystem (also applies if no subsystem available, e.g., a holding tank with 0 capacity).
($Z_C, Z_T, ZB_{T/D}, ZG_{T/D} = 0$)

Note:

In determining subsystem redundancy, the following criteria were utilized:

Collection Subsystem

- All ships with two (2) or more commodes are considered to have collection subsystem redundancy.

Transport Subsystem

- All WMS with CHT or Grumman treatment/disposal are considered to have transport redundancy.
- All WMS with Chrysler collection are considered to have transport redundancy only if two or more Chrysler systems are specified (since failure of treatment subsystem result in unavailability of purified oil for flushing).
- All WMS with GATX collection are considered to be redundant only if two or more M/T pumps are specified.
- All WMS with JERED collection are considered to be redundant if one (1) or more large boat VCT's are specified (two pumps for each large boat VCT) or two (2) or more small boat VCT's are specified (one pump for each small boat VCT).

Treatment/Disposal Subsystem

- All WMS with CHT subsystem for black/gray water are considered to have redundant T/D subsystems.
- All WMS with Chrysler treatment subsystem for black water are considered to have redundant T/D subsystems only if two (2) or more Chrysler units are specified.
- All WMS GATX treatment subsystem black water are considered to have redundant T/D subsystems only if two (2) or more evaporators are specified.
- All WMS with Grumman treatment subsystem for black/gray water are considered to have redundant T/D subsystem only if two (2) or more Grumman units are specified.
- All WMS with JERED treatment subsystem for black water are considered to have redundant T/D subsystems only if two (2) or more incinerators are specified.

Attribute Data

Rating

N/A - Not a viable system/vessel combination

Definition and values for $Z_{C/T}$, $ZB_{T/D}$, $ZG_{T/D}$

- (a) There are many fault-actuated mechanisms in WMS subsystem, or they are not required † ($Z_{C/T}$, $ZB_{T/D}$, $ZG_{T/D} = 4$)
- (b) There are some fault-actuated mechanisms in WMS subsystem ($Z_{C/T}$, $ZB_{T/D}$, $ZG_{T/D} = 2$)
- (c) There are no or almost no fault-actuated mechanisms in WMS subsystem ($Z_{C/T}$, $ZB_{T/D}$, $ZG_{T/D} = 0$)

* Include mechanisms to:

- (1) Alert operator/maintainer to high stress or abnormal condition that will result in failure.
- (2) Correct those conditions or turn off equipment.

† E.g., standard commodes and urinals in a gravity drain sewage collection subsystem do not require fault actuated cut-off mechanisms.

DISCUSSION OF THE EFFECTIVENESS ASSESSMENT METHODOLOGY AND APPLICATION GUIDELINES

EFFECTIVENESS ASSESSMENT OF CANDIDATES

The effectiveness of candidate systems is determined on the basis of numerous considerations such as system characteristics and features, assumptions, etc. It is very difficult to make sound decisions based on the simultaneous judgement of a multitude of considerations, many of which may be unrelated. On the other hand, it is fairly easy to make individual decisions on a small scale. The approach used for assessing the effectiveness of candidates is based on converting the relatively difficult problem of trying to arrive at a major decision by simultaneously juggling numerous and often unrelated considerations, into the relatively easy problem of systematically making many "small" decisions. The approach also addresses the necessity of combining the decision-maker's subjective judgements with technical data and relevant assumptions in arriving at an overall effectiveness assessment of each candidate system.

The effectiveness assessment consists of the following three basic steps:

- . Development of a suitable effectiveness model.
- . Development of effectiveness attribute data.
- . Quantification of effectiveness by substitution of the effectiveness attribute data into the effectiveness model.

The effectiveness model is, in effect, a framework of criteria for judging the degree of acceptability of each candidate system. This framework is in the form of a hierarchy which structures the effectiveness assessment criteria in successive levels of detail and specificity. A set of weights are then associated with this criterion hierarchy to indicate the importance of each criterion in relation to the others.

The underlying concepts of the approach for assessing the effectiveness of candidates are discussed in the following paragraphs. This discussion is presented in accordance with the breakdown of the effectiveness model into its constituent elements and includes guidelines for the development of each model element discussed.

Definition of Effectiveness and Associated Implications

The approach for assessing the effectiveness of candidates and the development of the effectiveness model which forms the basis for this assessment are closely related to the definition of effectiveness. In the context of this study effectiveness is not to be viewed as a fixed and pre-formulated expression in terms of some specific variables. Instead, the following definition of effectiveness is used:

- . The effectiveness of a candidate is broadly defined as its overall quality. This quality is determined on the basis of how well the candidate fulfills specified objectives, requirements and constraints. Furthermore, this overall quality can be quantified and the resulting number is the effectiveness rating of the candidate. The effectiveness rating is a quantitative measure of the degree to which the candidate has satisfied the aggregate of all the individual criteria for determining conformance with objective and requirements as well as their relative importance.

It is noted that the above definition of effectiveness implies the following:

- . It is necessary to specify objectives, requirements and constraints.
- . It is necessary to establish criteria for judging how well the candidates fulfill the objectives, requirements and constraints.
- . It is necessary to indicate the importance of the established criteria relative to one another.

- . It is necessary to quantify each individual criterion as well as the aggregate of all criteria and their relative importance. This quantification must be based on candidate attribute data (i.e., characteristics).

The development of the effectiveness model forms the basis for accomplishing the above objectives.

Elements of the Effectiveness Model

As noted in the previous discussion the development of the effectiveness model is the basis for assessing the effectiveness of candidate system/vessel combinations. Completion of the effectiveness model also provides the basis for developing the required effectiveness attribute data as well as for quantifying effectiveness.

The effectiveness model consists of the following elements:

- . Measures of Effectiveness (M/Es)
- . M/E weights
- . Factors and subfactors of the M/Es
- . Factor/subfactor weights
- . Effectiveness Rating Functions (ERFs) for the elementary factors/subfactors

Each one of the above elements of the effectiveness model is discussed in the following paragraphs. Guidelines for developing each model element are also given. In addition, the nature of the necessary effectiveness attribute data and the procedure for quantifying effectiveness are also discussed.

SELECTING MEASURES OF EFFECTIVENESS (M/Es)

Purpose and Definition of M/Es

Candidate systems for a given vessel class can be compared more readily if a numerical score for effectiveness is determined for each candidate. As a first step in the process of quantifying effectiveness, it is necessary to establish a set of Measures of Effectiveness (M/Es). The M/Es constitute the figures of merit or the set of overall criteria which will be used to judge how well each candidate system meets the requirements which are deemed to be important. M/Es are broadly defined considerations or realms of concern for the decision maker.

Required Properties of M/Es

A valid set of M/Es should be characterized by the following properties:

- . Appropriate level of comprehensiveness
- . Completeness
- . Uniqueness and Independence

Appropriate level of comprehensiveness implies that each M/E selected is sufficiently general to encompass or imply all the pertinent subcriteria which will subsequently be identified (the factors and subfactors). As an example, the number of man-hours required would not be an appropriate M/E since it is implied or encompassed by (and hence is subordinate to) another (and more general) figure of merit such as Operability or Maintainability.

Completeness implies that the M/Es selected (together) encompass all aspects which are considered to be important, i.e., they are, as a group, capable of assessing the candidate's qualifications with respect to all relevant criteria.

Uniqueness and Independence implies that none of the characteristics which are implied or included in one M/E appear in any one of the other

M/Es, i.e., there is no overlap in the various criteria (factors and sub-factors) which are implied by the selected set of M/Es.

Guidelines and Considerations in Choosing M/Es

When selecting a set of M/Es, it is important to keep in mind that these M/Es are not intended to be a universal and all encompassing set of figures of merit which are adequate for any conceivable set of circumstances. Instead, the M/Es should be based on the basic objectives and requirements at hand for the specific candidate system/vessel combination being studied. The following considerations should govern the selection of M/Es:

- . It is not necessary to decide in advance (or to know the details of) how each M/E will subsequently be broken down into its constituent factors and subfactors in order to choose an adequate set of M/Es. In fact, different individuals can be involved in these two processes.
- . Each M/E should represent an inherently different set of considerations or criteria.
- . They should be as few as possible in number, consistent with the goals of the study. No M/E should be included unless it is determined to be an essential consideration in assessing the effectiveness of the candidate systems. A proliferation of M/Es decreases the sensitivity of the overall effectiveness score for each M/E. Also, a multitude of M/Es makes it more difficult to make balanced judgements in assigning weights to the M/E. The number of M/Es used should be limited to less than ten.
- . A figure of merit which is a potential candidate for an M/E should not be eliminated from consideration on the basis of the argument that this M/E is not necessary because there are rigid requirements governing this area of concern which will take care of this problem. As an example, one may be tempted to argue that

"Safety" should not be made an M/E because there are specific regulations governing safety and an unsafe system will not be permitted to be installed on board a ship. The fallacies of such an argument are as follows:

- .. The fact is that irrespective of rigid specifications, unsafe equipments are to be found on board ships and accidents do occur.
- .. If the above argument is pursued to its logical conclusion, then all M/Es would be eliminated from consideration since there are also specifications for performance, reliability, habitability, operability, etc.
- .. Even if all candidates met the safety specifications (these can be considered as a minimum requirement), there are nevertheless substantial differences among candidates in the degree of safety and these differences should be identified and quantified.
- . It is usually easier to eliminate or add an entire M/E than it is to make numerous changes within several M/Es.
- . The relative importance or unimportance of each M/E will be stipulated via the weight assignment scheme.
- . The utility and ease of interpretation of the final results, i.e., the overall effectiveness score of each candidate system, will depend (among other things) on the care with which the M/Es and their weights are selected.
- . The wording used to describe an M/E should be concise and carefully chosen to ensure that the full meaning and all the criteria implied by the M/E are reflected in its name. A short statement of the issues implied by each M/E should be provided.

ASSIGNING WEIGHTS TO THE M/Es

Purpose of M/E Weights

Assignment of weights to the M/Es serves two essential purposes. First, these weights enable the decision maker to reflect his judgement as to the relative importance of each M/E, based on the candidate systems and the vessels being considered as well as the objectives and goals of the study. Thus, the M/E weights provide the decision maker with the opportunity to perform trade-offs between the different considerations governing the selection of a candidate system.

Second, assignment of weights to the measures of effectiveness facilitates the combination of the individual M/E ratings into an overall effectiveness rating for each candidate.

Guidelines for Assigning M/E Weights

Since the choice of weights has a strong influence on the overall effectiveness rating of the candidates and therefore influences the manner in which they will be ranked, the choice of M/E weights should be made by cognizant decision makers who are familiar with the considerations which were used to determine the specific choice of M/Es. Due to the importance of these M/E weights, great care should be exercised in their selection. Following are some guidelines for assigning M/E weights.

- . All of the subordinated levels of factors and sufactors within the effectiveness model structure do not have to be identified in order to assign M/E weights.
- . Weight assignments are to be system and vessel independent (knowledge of system or vessel characteristics is not required).
- . Weight assignments are to be used to convey the importance of each M/E relative to one another.

- Weight assignments are to indicate importance by assigning higher numbers to those M/Es that are more important and low numbers to those of lesser importance.
- Numbers should be assigned on a percentage basis (whole numbers only) and should range on a scale of 0-100%, with the sum of all weight assignments equal to 100%, i.e.,

$$W_1 + W_2 + W_3 + \dots + W_m = \sum_{i=1}^m W_i = 100$$

DETERMINING THE FACTORS AND SUBFACTORS OF EACH M/E

Each M/E encompasses a large number of considerations and hence depends on a multitude of candidate system attributes. As a result, it is not practical to attempt to obtain a direct rating for each candidate system with respect to the M/Es. Instead, each M/E is systematically broken down into its constituent component criteria and then a relationship between each of these component criteria and the candidate system's attribute is established.

Selecting Factors of an M/E

As a first step in this breakdown, a set of factors is selected to characterize each M/E. These factors, in combination, represent all the aspects or attributes of a candidate system which are considered to be relevant to the particular M/E. The set of M/E factors is not necessarily unique. In establishing such a set, it is important to ascertain that they are characterized by the following properties:

- Appropriate level of comprehensiveness
- Completeness
- Uniqueness and independence

* It is noted that these properties were also called for in the choice of the set of M/Es.

The first property is concerned with picking a set of factors which represent, in effect, a first indenture of each effectiveness measure, rather than a set of very detailed considerations which would be appropriate only at further levels of indenture. As an example of what is meant here, "special tool requirements" is an appropriate consideration which is implied by the M/E "Maintainability", but it would not be appropriate as a factor of this effectiveness measure because it is a consideration which is implied by the more general, and hence more appropriate, factor "Corrective Maintenance Requirements".

The second property is concerned with ascertaining that the factors chosen together constitute (i.e., imply) all aspects of the effectiveness measure which are considered to be important and relevant for that M/E. That is, the factors of an effectiveness measure must be capable of completely describing and characterizing it.

The third property is concerned with avoiding overlap in considerations which are implied by the different factors of an M/E, and to insure independence among factors, i.e., the rating of one factor is independent of the rating of any other factor.

Selecting Subfactors and Elementary Factors/Subfactors

The factors themselves may be too complex to assign ratings to them because they encompass a multitude of considerations. As an example, the factor "Corrective Maintenance Requirements" of the M/E "Maintenance" includes considerations such as labor, parts, accessibility, etc. The procedure which is followed in such cases is to break up each complex factor into a set of subfactors which, together, encompass all the considerations which are implied by the factor. In choosing a set of subfactors for each factor, the same considerations which govern the choice of factors for each M/E are employed, namely:

- . Appropriate level of comprehensiveness
- . Completeness
- . Uniqueness and independence

Often, subfactors may themselves be too complex because they imply numerous considerations and hence may require further breakdowns. This is accomplished by determining a set of lower level subfactors for each complex subfactor. The procedure employed is analogous to those used for determining the factors of each M/E, as well as those for choosing the subfactors of a complex factor, and the same criteria apply. This procedure of breaking down a complex subfactor into a set of lower level subfactors is continued successively as many times as necessary or convenient until a set of elementary subfactors (or factors) is reached. An elementary subfactor or factor is one which encompass a single consideration and hence can be rated by relating it to some attribute of the candidate system. As an example, "Accessibility of replaceable components" is an elementary subfactor of the subfactor "Ease of repair/replace", of the factor "Corrective Maintenance requirements", of the M/E "Maintainability". This is a single aspect of maintainability for which a direct relationship can be established between the magnitude of the candidate system attribute and a numerical rating for the elementary subfactor.

It is noted that the choice of elementary subfactors/factors is not always obvious or unique. As an example, the number of maintenance man-hours required may be chosen as an elementary subfactor. However, several maintenance personnel, at different skill levels may be assigned to the system/equipment whose maintainability is being analyzed. The question arises, then, whether the maintenance man-hour requirement should be further broken down by skill level or whether the sum of man-hours for all skill levels is sufficient. The decision on the extent of breakdown and therefore the level of the analysis depends upon a number of considerations, including the availability of data and the funding as well as the time available for the analysis.

Unique Identification of Factors and Subfactors

The levels of subordination of factors and subfactors are conveniently indicated by successive indentures and by the number of "bullets" appearing

in front of the factor or subfactor. Elementary factors/subfactors are those having the largest number of such "bullets" in front of them.

Usually, there are more than one factor or subfactor at any given level of subordination. In order to form a unique identification of each factor and subfactor, a numbering scheme is used as follows:

The number of digits indicates the level of subordination of the factor or subfactor.

The first digit represents the factors, the second digit represents the subfactors, the third digit represents subfactors of subfactors, etc.

The numerical value of each digit represents the sequence or position of the corresponding factor or subfactor in relation to the others at the same level from top to bottom, starting with 1 for the first, 2 for the second, etc.

Since the number of factors or subfactors at any given level of subordination will be limited to nine, the digits will range from 1 to 9. As a result, it is not necessary to have any separators between the digits in the number which designates the unique identifier for a given factor or subfactor.

ASSIGNMENT OF FACTOR/SUBFACTOR WEIGHTS

Purpose of Factor/Subfactor Weights

After the effectiveness measures are broken down into factors and subfactors and their associated levels of subordination, it is necessary to assign weights at each level of subordination. These weights serve two essential purposes. First, they provide a means of combining the ratings for the factors and subfactors in order to obtain an overall numerical rating for each effectiveness measure. Second, they provide an opportunity for the analyst to specify how much each factor and subfactor is to contribute to the effectiveness rating within each effectiveness measure. This complements the level structure of the effectiveness model, which shows the

breakdown of each measure of effectiveness into factors and successive levels of subfactors to indicate the manner in which the various criteria are related to one another in terms of subordinate levels of considerations. On the other hand, weights indicate how important each consideration is in relation to the others. Thus, the factor and subfactor weights allow the decision maker to perform trade-offs between relevant considerations.

Guidelines for Assigning Factor/Subfactor Weights

The approach for assigning factor and subfactor weights is similar to that used for assigning weights to the effectiveness measures. The basis for the weight assignment is subjective judgement guided by experience and knowledge of the candidate systems, the vessels and the objectives of the study. Weight assignments should be made in consultation with individuals most familiar with the pertinent criteria under consideration, i.e., the factor/subfactors of each M/E. Following are some guidelines for assigning factor/subfactor weights.

- Weights are assigned to each effectiveness measure systematically in a step-by-step manner, following the factor/subfactor level of subordination structure, beginning with the highest level, i.e., the factors of the effectiveness measures.
- Weights are assigned on a per level basis i.e., the distribution of weights among the factors or subfactors at a given level should not be influenced by the weights already assigned or those to be assigned to factors and subfactors at higher or lower levels.
- Weights are distributed to factors or subfactors at the same level on the basis of the importance of each factor or subfactor in relation to the others. The degree of importance is indicated by the numerical value assigned to the factor or subfactor weight, following the convention that a higher weight means greater importance and a lower weight means less importance.

- The numerical value of the factor/subfactor weights are given as a percentage on a scale from 0 to 100% (given to the nearest percentage point).
- Weights must be distributed among the factor/subfactors at the same level, taking relative importance into account, so that the sum of the weights at any given level is equal to 100, i.e.,

$$W_1 + W_2 + W_3 + \dots + W_n = \sum_{i=1}^n = 100$$

Factor/subfactor weights are system independent but may be vessel dependent, i.e., the distribution of weights at any given factor/subfactor level may be different for each vessel. This enables one to accommodate the fact that some considerations may be more important on one vessel than on another vessel.

DEVELOPMENT OF EFFECTIVENESS RATING FUNCTIONS (ERFs)

Purpose and Definition of ERFs

Having developed the structure of the effectiveness model, (consisting of a breakdown of each Measure of Effectiveness (M/E) into its factors and subordinate subfactors) and having assigned weights to the M/Es and to all factors and subfactors, it is necessary to determine a numerical effectiveness rating for the elementary factors/subfactors for each viable candidate system vessel combination in order to quantify each M/E as well as the overall effectiveness. Determination of numerical effectiveness ratings for each elementary factor/subfactor consists of the following three steps:

- . Development of an effectiveness rating function (ERF) for every elementary factor/subfactor within each M/ E.
- . Development of effectiveness attribute data for every viable candidate system/vessel combination, as required for input to each effectiveness rating function.
- . Use of the effectiveness attribute data for each viable candidate system/vessel combination as input to the effectiveness rating functions to obtain an effectiveness rating for every elementary factor/subfactor.

An effectiveness rating function establishes a generic relationship between a relevant quantitative or qualitative system/vessel characteristic, i.e., the "value" of the system/vessel attribute, and a numerical rating which expresses a subjective judgement of the "worth", "quality", desirability, adequacy, acceptability, preference, etc., of the attribute "value". The rating is a subjective indicator of how well each candidate fulfills (on a relative basis) the criterion established by the relevant elementary factor/subfactor. This is to be distinguished from the factor/subfactor weights which indicate how important (on a relative basis) each

criterion is. Establishment of the effectiveness rating functions constitutes the final step in the development of the effectiveness model. After this step has been completed, the quantification of effectiveness becomes a straightforward, although tedious, procedure which readily lends itself to computer implementation.

Steps in the Development of ERFs

Since the effectiveness rating functions (in conjunction with the M/E and factor/subfactor weights and levels of subordination) form the ultimate basis for quantifying the effectiveness of each viable candidate system/vessel combination, great care should be exercised in their development. The derivation of effectiveness rating functions requires a clear and thorough understanding of the criteria which are implied by the relevant elementary factors/subfactors, knowledge of the candidate system/vessel characteristics (attributes) and the manner in which they are "measured" as well as the ranges of "values" of the attribute data, and the use of subjective judgement as to what constitutes "good" and "poor" attribute "values" for candidate system/vessel characteristics. The development of effectiveness rating functions consists of the following three basic steps:

- . Determine the system/vessel characteristic which will serve as the effectiveness attribute variable to be used as a "measure" of the criterion implied by the relevant elementary factor/subfactor. This step may entail an intermediate step which combines two (or more) different types of raw system/vessel characteristics, e.g., the use of skill weighted man-hours as a measure of the burden on the vessel crew for system operation and maintenance, or the use of system weight and its location within the vessel to determine the moment as a measure of the effect on vessel stability, trim or list. Effectiveness attribute variables may be system dependent only (e.g., odor, noise, etc.) or system and vessel dependent (e.g., moment). System/vessel attribute variables may be quantitative (e.g., dimensions in feet, number

of man-hours required for operation/maintenance, the number of different spare part types required) or they may be qualitative (e.g., odor or noise produced by system, complexity of system). Quantitative effectiveness attribute variables may be continuous (e.g., weight of system, consumption of fuel, etc.) or they may be discrete (e.g., the number of skill levels required for operation/maintenance, the number of duplicate systems required, etc.).

Determine the format, i.e., form and shape, of the functions to be used in relating "values" of the effectiveness attribute variable on the horizontal axis to rating numbers on the vertical axis which are a measure of the "worth" or degree of "goodness", the "desirability", etc., of the corresponding "value" of the attribute variable. This step requires the use of subjective judgement to determine what constitutes "good" and "poor" "values" for the pertinent system/vessel attribute variable. It also requires determination of the "rate" at which changes in attribute values are to be "rewarded" or "penalized", i.e., it requires that a rating number be assigned to every possible "value" of the attribute variable. The ratings are numerically expressed as a percentage, on a scale ranging from 0 to 100%, using the convention that a high rating represents a favorable condition and a low rating represents an unfavorable condition (i.e., an undesirable value of the attribute variable).

Determine the "limits" ("upper" and "lower") of the rating function. This is based on subjective judgement of what constitute "acceptable" and "unacceptable" system/vessel "values" for the attribute variable.

Criteria and Guidelines for Developing ERF's

The development effectiveness rating functions is, to a large extent, an art and as a result the quality of the rating functions is dependent on the ingenuity, creativeness and resourcefulness of the analyst. It is noted that this also applies to the development of the structure of the effectiveness model. As a result, a step by step systematic procedure for formulating effectiveness rating functions cannot be given. Instead, guidelines and assessment criteria for the development of effectiveness rating functions will be given.

Following are some criteria for judging the quality of an effectiveness rating function. An elegant rating function is characterized by the following qualities:

- . It directly addresses the intended criterion and encompasses all the issues implied by the elementary factor/subfactor.
- . It is simple, i.e., the rating procedure is transparent (visible) to the reader without resorting to elaborate explanations, and the reader can relate to it readily (i.e., the reaction is that it is "obviously" the way to do it, after he sees how it was done).
- . It highlights and emphasizes differences and suppresses similarities between candidate system/vessel combinations.
- . It is consistent with the effectiveness attribute data availability, i.e., it does not require data which are not readily available and makes use of all pertinent data which can readily be obtained.
- . It has a relatively high degree of repeatability (with respect to time and across individuals), especially for subjective criteria.

Following are some guidelines for developing effectiveness rating functions for elementary factors/subfactors.

- It is not necessary to be familiar with the details of the structure of the effectiveness model, or the associated M/E and factor/subfactor weights, in order to formulate cogent rating functions.
- It is not necessary to have the actual system/vessel attribute data available in order to formulate the concept and general shape of the effectiveness rating function. However, full definition of a rating function may have to await determination of the effectiveness attribute data for all viable candidate system/vessel combination in order to fix limits, ranges, extreme points, function shape, etc.
- The purpose of effectiveness rating functions is to measure "how good" a system/vessel characteristic is. Rating functions are not concerned with "how important" that characteristic or feature is (this aspect is handled by the factor/subfactor weights).
- Effectiveness rating functions for elementary factors/subfactors should be structured such that a higher numerical rating means "better", "more favorable", "more adequate", etc., and a lower numerical rating means "worse", etc.
- Ratings of elementary factors/subfactors (i.e., the result of substituting system/vessel effectiveness attribute data into a rating function) will be expressed as a percentage ranging from 0 to 100%. Ratings should be given to the nearest percentage point.
- Effectiveness rating functions are always system dependent and may or may not be vessel dependent too.
- Ideally, effectiveness rating functions which measure consumption of vessel resources (fuel, electric power, space, man-hours, etc.) should be related (normalized) to vessel capacity, rather than using a normalization scheme based on the maximum value.

- Vessel dependence of an effectiveness rating function can be handled by one of the following methods:

- .. Prepare separate curves for each vessel or show a family of curves on the same set of axes with the vessel as the parameter.
- .. Use a generalized effectiveness attribute variable which incorporates the vessel dependence in it (e.g., WMS electric power consumption expressed as a percentage of the whole or a fraction of the vessel generating capacity).
- .. Use an effectiveness attribute variable which incorporates the vessel dependence as an explicit parameter to be entered when evaluating a given system/vessel combination, i.e., the actual position of a given system/vessel combination on the attribute scale becomes fixed when the vessel parameter (in addition to the system attribute value) is substituted.

- Effectiveness rating functions should be consistent with the availability of system/vessel effectiveness attribute data, it should utilize the data which is readily available to the maximum extent but should not place an undue burden on data requirements by specifying data which is either unavailable or is impractical because it requires an unwarranted effort or expense to obtain.
- An effectiveness attribute variable may itself be a function of other raw system/vessel attribute variables (e.g., weighting man-hours by skill level to obtain a skill weighted labor requirement, etc.).
- A primary purpose of effectiveness rating functions is to highlight differences between system candidates rather than to show similarities. This should be taken into account when structuring rating function shapes, establishing ranges, extreme points, etc.

- In rating certain undesirable attributes, consideration should be given to system/vessel conditions which facilitate easy elimination or alleviation of the problem (e.g., better ventilation to remove odor and heat, better shock mounts to reduce vibration, etc.) by "penalizing" such system/vessel combinations less than those which do not have this property.

- Effectiveness rating functions which depend on subjective judgments should take into account the tendency of most people to provide answers which tend toward the average. This can be counteracted by providing many response choices at the extremes (good/bad, high/low, much/little) and few at the midpoint or average.

- Difficult (conceptually or otherwise) effectiveness rating functions are probably best done in stages rather than investing a lot of time trying to formulate it during the first attempt.

- Effectiveness rating functions and the form of the required attribute data should be transparent (visible) to the reader. If intermediate steps are used to convert the necessary raw attribute data to the required format, these steps should be clearly indicated. Unless there are compelling or overriding considerations, rating function shapes should be simple curves (a shape which is readily "understood" by the reader). Examples of overriding considerations which would warrant more complicated rating function shapes is a priori knowledge that the effect under consideration is a non linear function (i.e., it varies as the square, the square root, exponentially, etc.) of the attribute variable. Such a non linear functional relationship may also be used to "penalize" or "reward" a candidate system/vessel combination which has "good" or "poor" values for the attribute variable.

Some Examples of ERFs

Examples of possible effectiveness rating function shapes are shown in Figure 5. The functions represented by (a), (b), (c) and (d) in Figure 5 are for effectiveness attributes which are continuous variables. The functions represented by (e) and (f) are for attributes which are either discrete variables or for continuous variables for which ratings are more readily assigned to ranges of the variable instead of to every possible value of the variable. The functions represented by (g) and (h) are for attribute variables whose "values" are not numerical but represent either qualitative information or yes/no answers to specific questions. Functions represented by (a), (b), and (e) are such that the higher the value of the attribute variable, the lower the rating and vice versa, i.e., low values of the attribute are favorable and high values are unfavorable (e.g., total man-hours required for maintenance, the total number of different skill levels required). The functions represented by (c), (d) and (f) are such that the higher the value of the attribute variable the higher the rating and vice versa, i.e., high values of the variable are favorable and low values are unfavorable (e.g., MTBF of an equipment). Functions (a) and (c) are representative of attribute variables which have an upper limit, whereas functions (b) and (d) are representative of variables which do not have an upper limit. It is noted that an attribute variable may inherently not have an upper limit yet be represented by a function which shows an upper limit. An example of such a situation is an attribute variable such as total maintenance man-hours which has been normalized by dividing the value for each candidate either by the highest value or by a fraction of a year or by the vessel complement (or fraction thereof). The value used for normalization thus becomes the upper limit. Function (g) is representative of an attribute variable which is qualitative in nature and the "values" of the variable are degrees of "goodness" in comparison to some specified standard (e.g., the odor level generated by the WMS fixtures, in comparison to standard household fixtures). Function (h) represents an attribute variable whose "values" are yes/no answers to a specific question (e.g., "are special tools required?").

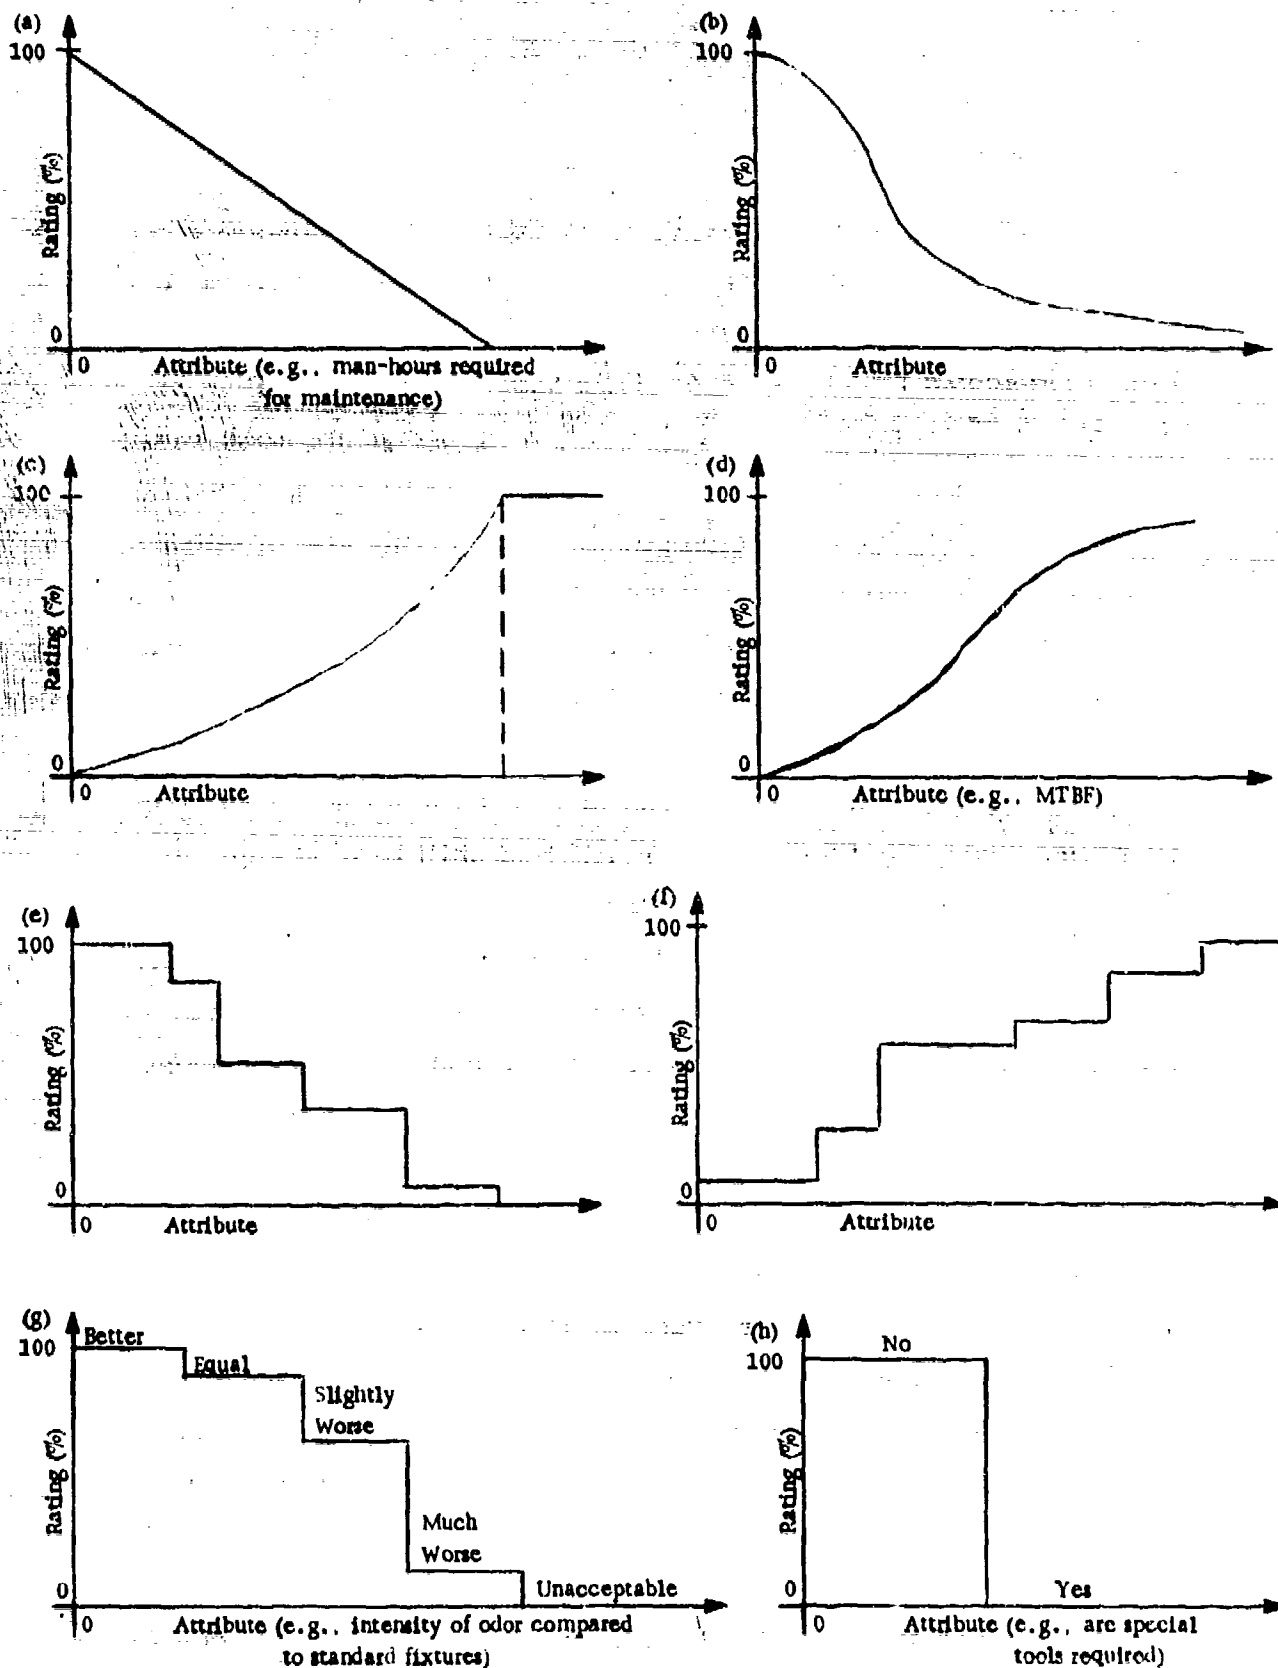

Figure 5

EXAMPLES OF EFFECTIVENESS RATING FUNCTION SHAPES
FOR ELEMENTARY FACTORS/SUBFACTORS

The sample functions presented in Figure 5 are suggestive of the procedures used for rating elementary factors/subfactors. The actual functions to be used in any given problem have to be determined by the analyst on the basis of his familiarity with the candidate system/vessel combinations involved, the data available, his experience and judgement.

Further examples of effectiveness rating functions are provided in Figure 6 which shows ratings of some automobile characteristics which may be of interest to some users. The function in (a) attempts to rate automobile fuel economy. This rating function indicates that an automobile getting less than 5 miles/gallon is considered to be unacceptable (a rating of 0%), whereas an automobile which yields 40 miles/gallon or more is considered to have the maximum rating of 100%. Automobiles which have fuel economies within the range of these two extremes are rated on a linear scale sloping from 0 to 100%. The functions in (b), (c), and (d) for rating automobile range, stopping distance and acceleration, respectively, are based on the same principle. The rating function in (e) for rating handling and steering are subjective estimates based on comparison to an implied standard, in this case, the "average" of all automobiles. The rating function in (f) for arrangement and labeling of instruments is based on an absolute (as opposed to comparison) qualitative subjective estimate. The rating function in (g) for safety features such as the existence of reinforcement or a collapsible steering column is a two valued (0 or 100%) rating function based on the answer to a yes or no question.

"Difficult" ERF's and Repeatability

It is recalled that an elementary factor or subfactor is one that encompasses a single consideration or criterion and hence can be rated by relating it to some characteristic or attribute of the candidate system/vessel combination. However, there are circumstances in which the formulation of a rating function, which requires subjective assessment of the attribute, is complicated by the fact that the elementary factor/subfactor depends on

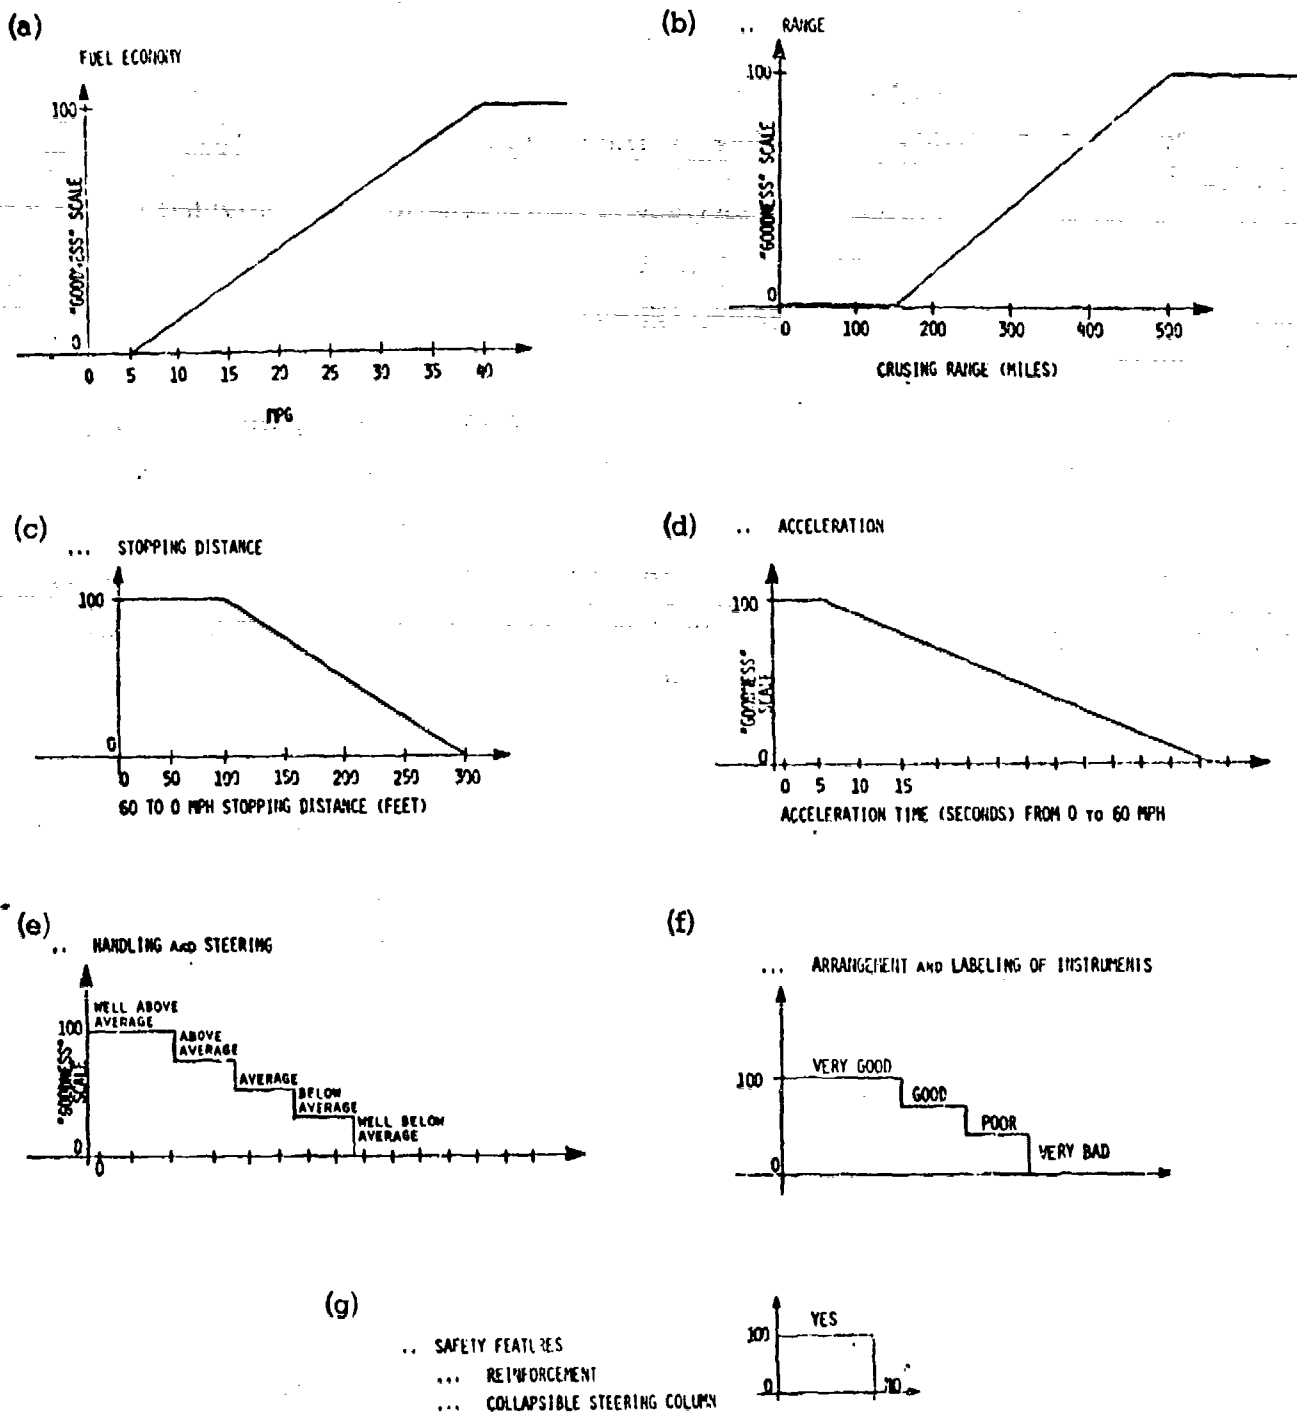

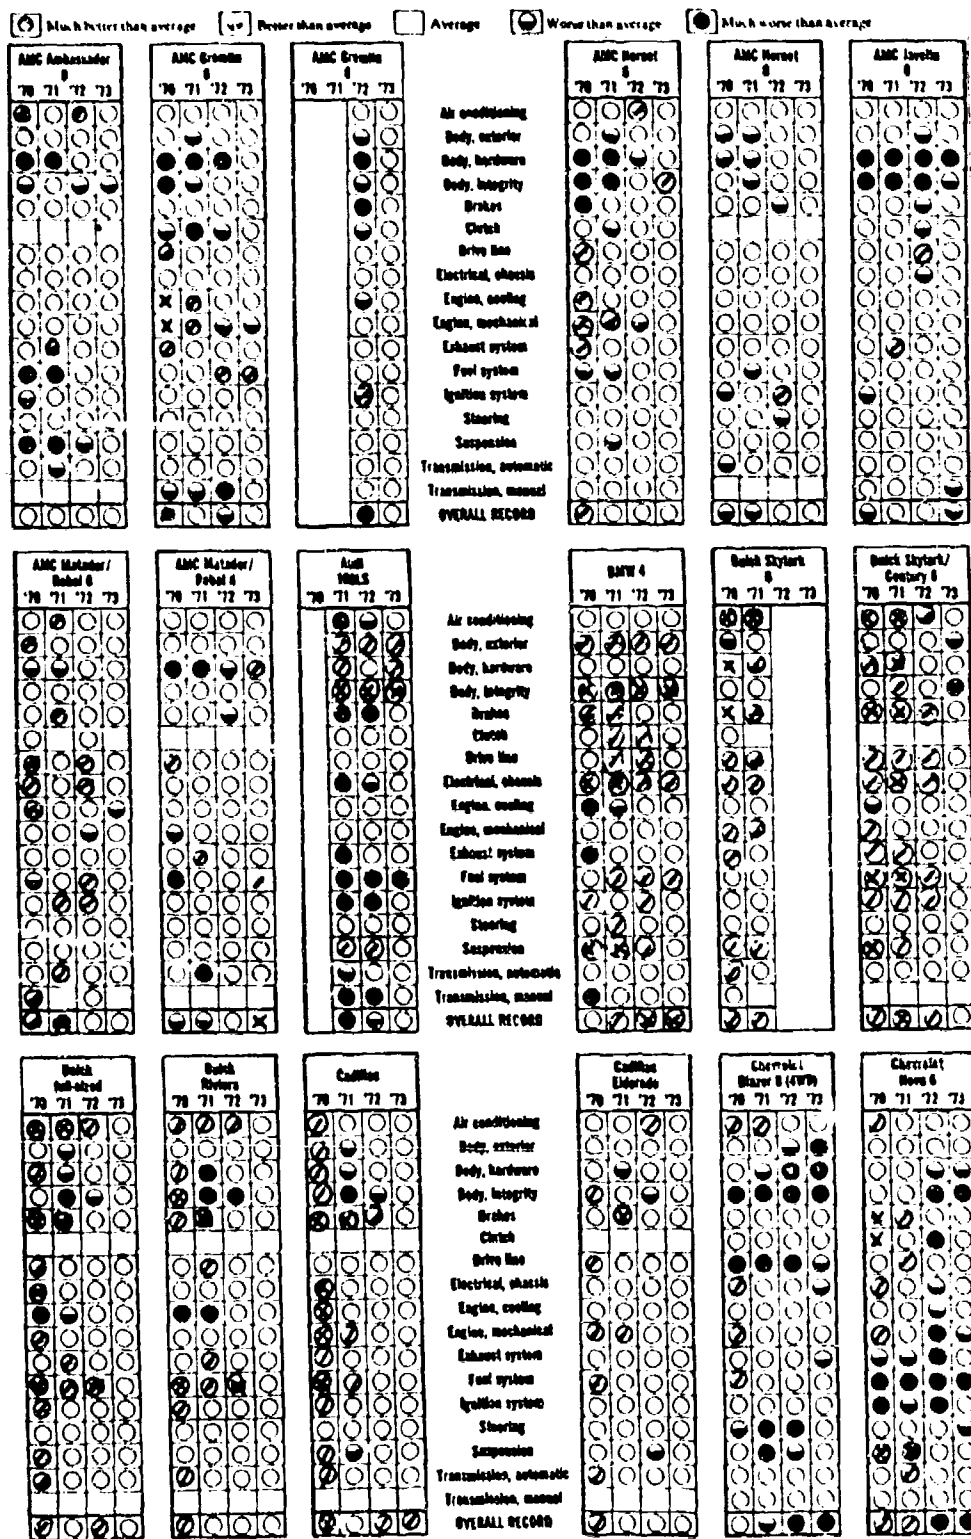

Figure 6
EXAMPLES OF EFFECTIVENESS RATING FUNCTIONS
FOR AUTOMOBILE CHARACTERISTICS

more than one variable (e.g., the effect of foreign objects based on a lengthy list of objects), or the data available for a single variable is elaborate.

An example of such a circumstance is presented in Figure 7 which provides data on automobile frequency of repairs, broken down by subsystem. The frequency of failures for each automobile function or subsystem is given as one of five possible levels or degrees and are designated by circles which are either blank or have in them crosses, slashes, partial and full shading. Note that one would find it difficult to use this information directly to rank the automobiles with respect to reliability, especially when a fair number of candidate automobiles are involved. It is further noted that even if one were somehow able to rank the reliability of the automobiles at a given time, the repeatability of such a ranking, even by the same individual, at a later time would be relatively poor. Finally, it is noted that even if one somehow managed to rank the automobiles on the basis of reliability so that a given candidate is more reliable than another candidate, one would find it extremely difficult to answer the question by how much?

Before proceeding to a proposed approach for developing effectiveness rating functions for situations of this type, it is worthwhile to examine what makes this example (and others similar to it) "difficult". The problem is that there are subjective elements and many mechanical elements and the usual thought process is such that the two are intermingled and decisions are made on the basis of an unclear mix of the two. Hence, the reason for poor repeatability because the mechanical elements, although simple, may be numerous and therefore overpower the subjective elements, although they may be few in number. In the above example, the subjective elements are the relative importance of each subsystem and the "worth" of each level of frequency of failure. The mechanical element is the "count" of the number of symbols of each type for a given candidate automobile.

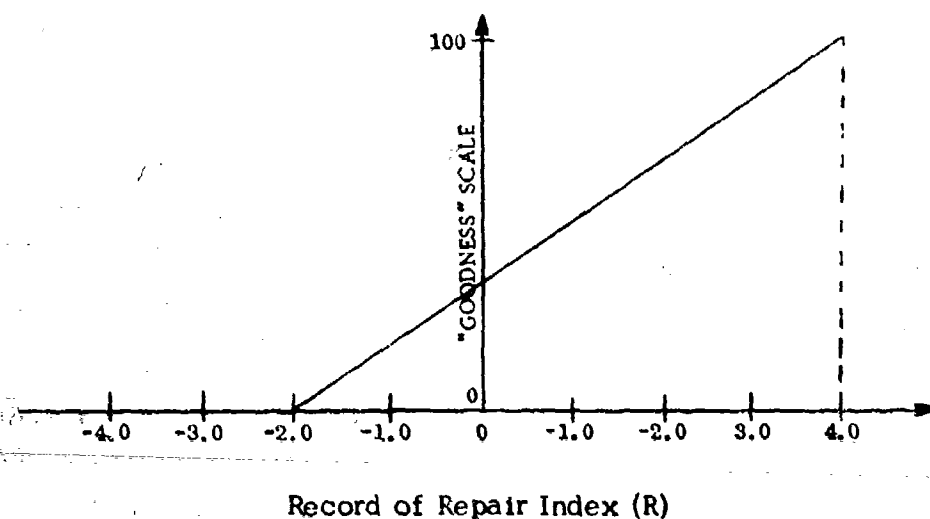

The solution to the problem of formulating effectiveness rating functions for "difficult" situations of this type is to proceed as follows:

- . Identify and separate the subjective and the mechanical aspects clearly and concisely.
- . Carefully pinpoint and study the subjective elements and make judgements relative to these elements only. Carefully document these judgements and the reasoning behind them, if any.
- . Develop a numerical procedure for systematically combining the subjective and the mechanical elements to yield a rating for a given candidate.

An example of the application of the above principles to formulate an effectiveness rating function for automobile reliability based on failure frequency data is presented in Figure 8. It is noted that the effectiveness rating function in Figure 8 is based on the following subjective judgements:

- . The "importance" (on a relative basis) of each subsystem (W_i).
- . The "worth" (D) of each possible reported ranking of failure frequency, i.e., much better than average (\oplus), better than average (\odot), average (O), worse than average (\ominus), much worse than average (\ominus).
- . The "range" of acceptable values for the attribute variable, which was chosen to be a Record of Repair Index (R) obtained as the sum of products of the importance (W_i) and the "worth" (D_i) of each subsystem for each year of reported data. This "range" was obtained by choosing a "minimum acceptable" value for R of -2.0 (from a possible "lowest" value of -4.0) and the maximum possible value for R of $+4.0$, which is considered to be "ideal". A linear relationship was chosen for rating candidate automobiles whose Record of Repair Index (R) falls in between these two limits.

$$R = \sum_1 W_1 D_1, \text{ where}$$

i - Subsystem identification

D_1 - Reliability of subsystem 1 based on repair record.

D_1 takes on discrete values from +1.0 to -1.0 in steps of .5, based on repair record as follows:

Symbol	<u>D</u>	<u>Interpretation</u>
⊗ CROSS	↔ +1.0	Much better than average
⊘ SLASH	↔ +0.5	Better than average
○ BLANK	↔ 0	Average
◐ BLACK	↔ -0.5	Worse than average
● BLACK	↔ -1.0	Much worse than average

W_1 - Weight (importance) of subsystem 1. The values of W_1 are chosen so that

$$\sum_1 W_1 = 1.0 \text{ (100\%)}$$

Figure 8

EFFECTIVENESS RATING FUNCTION FOR AUTOMOBILE RELIABILITY

It is noted that once the above subjective judgements have been made, together with the definition of the attribute variable (the Record of Repair Index, R) the rating of the reliability for any given candidate automobile is not only purely mechanical, straightforward and systematic but it is also perfectly repeatable. It is suggested that the overall repeatability of the ratings, with the inclusion of the subjective elements, is much higher with the use of this approach than it would be without it, i.e., on the basis of a direct visual comparison of the failure frequency data for each automobile. Furthermore, the above scheme for rating automobile reliability not only ranks the candidates with respect to reliability, but it also indicates "by how much" one candidate is "more reliable" than any other candidate on a relative basis, which results from using the same rating procedure for each candidate.

A final comment on the above example involves the treatment of missing data. The amount of data available may not be the same for all candidate automobiles. This may be due to the fact that some models may have been introduced during the years for which failure frequency data was collected, or insufficient data may be available for some models or for some of the subsystems of some models due to inadequate user response. Since the value of the attribute variable, the Record of Repair Index (R) must be based on the same amount of data for all candidates in order for it to have a consistent interpretation with respect to relative magnitudes, it is necessary to fill in the "missing" data (whether real or artificial). The procedure which may be adopted for filling in missing data depends on one's attitude toward data which is unavailable. That is, one can be an optimist and assume that if the data were available, it would be favorable, or use the argument that since the facts are not known it is "unfair" to assume that the data would tend to penalize the system. On the other hand, one can be a pessimist and assume that if the data were available, it would be unfavorable, or use the argument that unavailability of data is as bad as available unfavorable data since the decision has to be made now and

cannot be deferred until such time that data does become available. Another possible approach, perhaps in between the above two extremes, is to use some procedure which fills in the missing data with the "average" of the available data. If the missing data is for one or more entire year then one can determine a value of R based on 2 or 3 years and apply a scaling factor (of 2 or 4/3) to convert it to an equivalent R based on 4 years of data.

Simplified ERFs Based on Ranking

The procedures described above for rating elementary factors and sub-factors may not be practical in certain situations due to one of the following reasons.

- Quantitative data is not available.
- A simpler and quicker rating procedure is warranted due to the relatively high level of the analysis, e.g., during the early stages of the system life-cycle (such as during concept formulation).
- The unavailability of sufficient time and/or funding for a detailed analysis.
- The ratings are based on highly subjective attribute data which require difficult judgement.

Instead, a simplified rating procedure is desired.

The simplified elementary factor/subfactor rating procedure is based on a ranking of the candidates. This approach is relatively fast and simple to use, however, some accuracy is sacrificed. The procedure consists of two simple steps. First, the candidates are ranked with respect to the attribute, starting with one (1) for the "best", two for the "second best", etc. The elementary factor/subfactor rating (R) is then determined from the relationship

$$R = 100 \left(1 - \frac{1}{n+1} \right), \text{ where}$$

i = Rank of the candidate

n = The total number of candidates

In order to illustrate the use of the rating procedure based on a ranking of candidates and to point out the associated loss of accuracy, consider the following example. The effectiveness of three candidate systems is being evaluated for the effectiveness measure "Maintainability" in which one of the elementary subfactors depends on the system attribute man-hours consumed per year.

Assume that the three candidate systems (A, B and C) have the following values of this attribute:

<u>System</u>	<u>Attribute (Man-Hours)</u>
A	500
B	15
C	5

A ranking procedure, assuming that a lower man-hour requirement is more desirable, would assign the following ranks to the above systems:

<u>System</u>	<u>Attribute (Man-Hours)</u>	<u>Rank</u>
A	500	3
B	15	2
C	5	1

These rankings are then converted to effectiveness ratings in the range from 0 to 100% by the following relation:

$$\text{Rating (Man-Hours)} = \left(1 - \frac{[\text{System Rank (Man-Hours)}]}{4}\right) 100$$

The above relationship yields the following results based on ranking:

<u>System</u>	<u>Attribute (Man-Hours)</u>	<u>Rank</u>	<u>Rating (Man-Hours) - %</u>
A	500	3	25
B	15	2	50
C	5	1	75

These results indicate that the three systems are different and that System B is "better" than System A and that System C is "better" than System B. These conclusions are consistent with what one would expect based on an examination of the raw data presented. However, the results indicate an "equal" difference of 25% between Systems A and B, and between Systems B and C. This conclusion contradicts what is intuitively expected on the basis of the raw data.

To illustrate the type of results provided by a rating which is based on the absolute value of the attribute data rather than on a ranking, consider the simple rating scheme which subtracts the relative magnitude of the attribute (normalized by dividing each by 1000 man-hours) from 1.0, namely:

$$\text{Rating (Man-Hours)} = (1 - \frac{\text{Magnitude of Attribute (Man-Hours)}}{1000}) 100\%$$

The above evaluation scheme yields the following results:

<u>System</u>	<u>Attribute (Man-Hours)</u>	<u>Rating (Man-Hours) - %</u>
A	500	50
B	15	98.5
C	5	99.5

These results again indicate that System B is "better" than System A and that System C is "better" than System B. However, the results also indicate that the difference between Systems B and A is much greater than the difference between Systems C and B. This is more in accordance with the type of results which are intuitively expected on the basis of an examination of the raw data.

Comparison of the effectiveness ratings based on a ranking scheme with those based on the absolute value of the attribute data indicates the essential differences and similarities between these two methods of rating elementary factors and subfactors. Both methods are capable of answering the question:

which system is 'better'? However, the conventional effectiveness rating scheme is also capable of answering the question: "By how much?", whereas the rating scheme based on ranking obscures degrees of difference between the candidates.

Simplified ERFs Based on Qualitative Assignments

The effectiveness rating functions discussed earlier are generally based on having either explicit quantitative system/vessel attribute data or qualitative/subjective data based on comparing all candidates to either a specified standard or to one another (ranking). A very simple type of effectiveness rating function can be formulated on the basis of absolute qualitative assignments based on subjective judgements. An example of such a rating function is presented in Figure 6 (f), which rates the adequacy of the arrangement and labeling of instruments in an automobile. The rating process simply consists of deciding for each candidate that the instrument arrangement and labeling is characterized best as very good, good, poor, very bad.

The procedure for formulating effectiveness rating functions based on qualitative assignments consist of two simple steps as follows:

- . Choose a number of absolute qualitative levels or degrees of "goodness" to characterize the system/vessel attribute under consideration (e.g., excellent, good, acceptable, poor, unacceptable).
- . Determine the "worth", on the rating scale, expressed as a percentage ranging from 0 to 100%, of each of the qualitative levels of acceptability chosen to characterize any candidate system/vessel combination.

It is noted that this approach for formulating effectiveness rating functions has the advantage of being quick and easy to develop. It may be used in a situation which requires a quick preliminary analysis when data

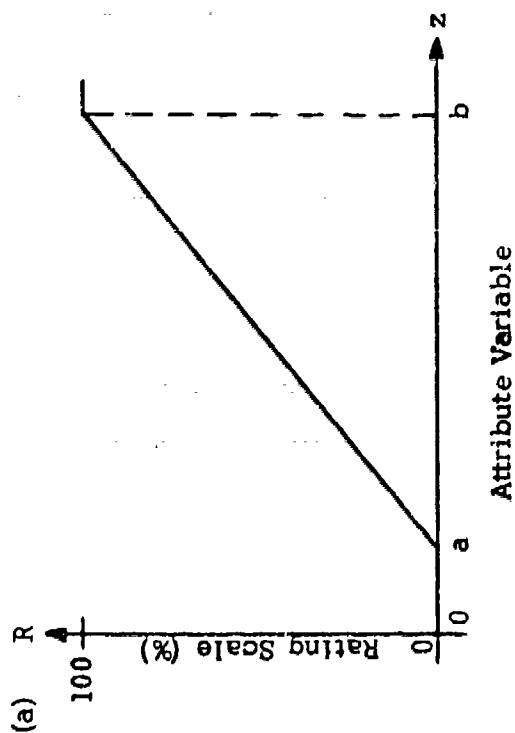

is either unavailable or the effort to obtain it is not warranted. This procedure may also be warranted when the attribute data, even in the context of a detailed analysis, is inherently qualitative and/or highly subjective.

This effectiveness rating procedure for elementary factors/subfactors may also be used as a last resort when all other approaches fail for any reason. A disadvantage of this approach (as is the case with effectiveness rating functions based on ranking) is that when used in conjunction with available quantitative attribute data, the degrees of differences between candidate systems are not adequately reflected because the rating is not based on the actual value of the attribute data but rather on a predetermined value. Another disadvantage is that this rating procedure is highly subjective and may result in relatively poor repeatability.

A Generalization for ERFs

It is noted from the earlier discussions that the formulation of effectiveness rating functions (ERFs) could be difficult, time consuming and may require a great deal of ingenuity due to the variety of different types of ERFs. While the development of ERFs could not be reduced to a simple, mechanical procedure requiring no investment of creative thinking, it is possible to outline a systematic procedure which can be followed to arrive at a formulation of the desired ERFs. Furthermore, this systematic procedure is sufficiently general to accommodate all types of ERFs usually encountered, as well as the different types of effectiveness attribute data associated with the different types of ERFs. As will be seen, this generalized approach reduces the entire process of formulating ERFs to one of choosing an appropriate attribute variable as well as its lower and upper limits. All the rest follows automatically.

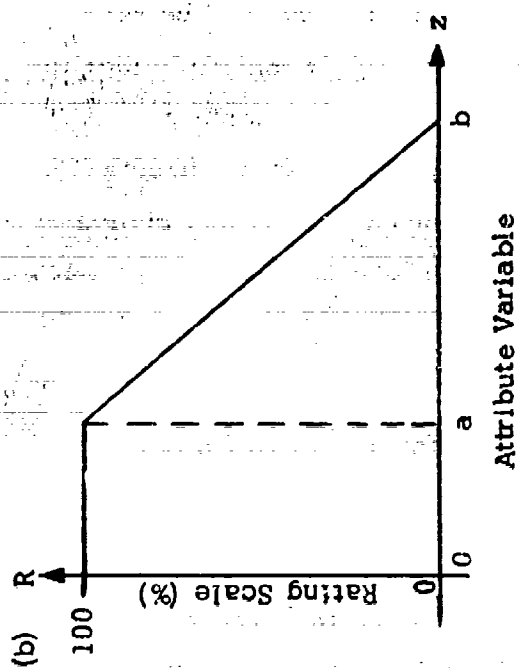

The format of the generalized ERF is depicted in Figure 9. The generalized ERF in (a) is used for attribute variables of a type for which a larger value is more favorable (i.e., represents a "better" candidate) than lower values, and (b) is used for attribute variables of the type that "reward"

$$R = 0, z \leq a$$

$$R = \frac{100}{(b-a)} (z-a), a < z < b$$

$$R = 100, z \geq b$$

$$R = 100, z \leq a$$

$$R = 100 - \frac{100}{(b-a)} (z-a), a < z < b$$

$$R = 0, z \geq b$$

Figure 9
GENERALIZED EFFECTIVENESS RATING FUNCTIONS

systems which have lower values of the attribute variable. As will be seen shortly, the linear relationships of the ERFs in (a) and (b) do not imply that the ERF chosen will result in a linear relationship between the elementary factor/subfactor rating (R) and the associated raw system/vessel attribute data. Non-linear relationships are readily established by the proper choice of an appropriate attribute variable (z).

As was indicated previously, the important issue is the formulation of the attribute variable z which in turn could be a function of one or more system/vessel characteristics or attributes. The concepts involved can best be described through a number of examples.

Consider first the case in which the attribute variable is a function of a single system/vessel characteristic x. As an example, the system/vessel characteristic or raw attribute data x could be the holding time of a WMS expressed as a percentage of the maximum holding time required for the vessel. If one did not have a strong opinion regarding the "worth" of holding times less than 100%, then one might choose to use a linear relationship between holding time and effectiveness rating, R, by relating the attribute variable z to the system characteristic x linearly, i.e.,

$$z = x$$

This yields an ERF of type (a) in Figure 9, in which $a = 0$, $b = 100$ and a functional relationship of the type

$$R = z = x, \quad 0 \leq x \leq 100$$

If, however, one felt that a holding time close to 100% is "worth" a lot and hence candidate systems should be greatly "rewarded" for "good" holding times, then one might decide to relate the attribute variable z to the system characteristic x by

$$z = x^2$$

This yields an ERF of type (a) in Figure 9, in which $a = 0$, $b = 10,000$ and a functional relationship of the type

$$R = \frac{100}{10,000} \quad z = \frac{x^2}{100}, \quad 0 \leq x \leq 100$$

If one felt even stronger about the value of "good" or "poor" holding times, then one could emphasize differences in system holding times even to a greater extent by using the relationship

$$z = x^n, \quad n = 3, 4, \dots$$

The resulting ERF would then be (with $a = 0$, $b = 100^n$)

$$R = \frac{100}{100^n} \quad z = \frac{x^n}{(100)^{n-1}}, \quad 0 \leq x \leq 100$$

Another way to accentuate differences is to use an exponential relationship between holding times and system ratings by choosing a relationship of the type

$$z = e^x$$

The resulting ERF would be (with $a = 1$, $b = e^{100}$)

$$R = \frac{100}{(e^{100} - 1)} (z - 1), \quad 1 \leq z \leq e^{100}$$

$$R = \frac{100}{(e^{100} - 1)} (e^x - 1), \quad 0 \leq x \leq 100$$

On the other hand, if one felt that changes in holding times from system to system should be deemphasized, then one could choose a relationship of the type

$$z = \sqrt{x},$$

which would result in an ERF of the type (with $a = 0$, $b = \sqrt{100} = 10$)

$$R = \frac{100}{10} z = 10 \sqrt{x}, \quad 0 \leq x \leq 100$$

Further deemphasis can be obtained by using a relationship of the type

$$z = \sqrt[n]{x}, \quad n = 3, 4, \dots,$$

which would yield an ERF of the type (with $a = 0$, $b = \sqrt[n]{100}$)

$$R = \frac{100}{\sqrt[n]{100}} z = \frac{\sqrt[n]{x}}{100^{\frac{1}{n}} - 1}, \quad 0 \leq x \leq 100$$

Even greater deemphasis can be obtained by relating z and x logarithmically as follows:

$$z = \log(x + c), \text{ where } c \text{ is an arbitrary positive constant}$$

This would result in an ERF of the type (with $a = \log c$, $b = \log(100 + c)$)

$$R = \frac{100}{\log(100 + c) - \log c} (z - \log c), \quad \log c \leq z \leq \log(100 + c)$$

$$= \frac{100}{\log\left(\frac{100}{c} + 1\right)} (\log(x + c) - \log c)$$

$$R = \frac{100 \log\left(\frac{x}{c} + 1\right)}{\log\left(\frac{100}{c} + 1\right)}, \quad 0 \leq x \leq 100$$

In the above examples, x was assumed to be a continuous variable. However, the procedure outlined above for ERFs is sufficiently general to accommodate system/vessel attribute data which are represented by discrete variables.

A generalization of this procedure is provided by the situation in which the system/vessel attribute data consists of a set of numbers x_i , $i = 1, 2, \dots, n$ (e.g., the number of parts required from each category i or historical data representing equipment failure times). The attribute variable may be chosen as the average value of x , i.e.,

$$z = \bar{x} = \frac{1}{n} \sum_{i=1}^n x_i$$

or the k^{th} moment of x , i.e.,

$$z = \frac{1}{n} \sum_{i=1}^n x_i^k, \quad k = 2, 3, \dots$$

Another possibility is to apply a weight to each value of x_i (e.g., the average periodicity of maintenance activities weighted by the duration of each activity) and use an attribute variable of the type

$$z = \frac{\sum_{i=1}^n w_i x_i}{\sum_{i=1}^n w_i}$$

As a further generalization of the approach for formulating ERFs, consider the situation in which the system/vessel attribute data is characterized by two (or more) variables. An example of such a situation may be an ERF for evaluating the personnel safety of candidate system/vessel combinations with respect to a given hazard. The safety may be characterized by the following two variables:

- x_1 - The likelihood of the occurrence of the hazard, which takes on any one of a specified set of n discrete numbers
- y_1 - The intensity level of the hazard, which takes on any one of a specified set of k discrete numbers

The attribute variable can be chosen as a Hazard Index defined as

$$z = x_1 y_1$$

It is clear that z is a discrete variable which can take on any one of $n(k)$ values. The generalization of this procedure to more than two variables is obvious.

In the above examples, the procedure for formulating an ERF consists of proceeding as follows:

- Choose the functional form of the attribute variable z in terms of the x_i , i.e., choose the functional form of

$$z = f(x_1, x_2, \dots, x_n)$$

- Determine the ERF type which is applicable, i.e., either type (a) or (b) of Figure 9.
- Determine the lower and upper limits of z , a and b , respectively. The lower limit will yield a rating R of 0 and the upper limit will yield a rating R of 100%, or vice versa.
- Draw a straight line with slope $\frac{100}{b-a}$ for the relationship of the rating R in terms of the attribute variable z in the range a to b . This graph or analytic expression can then be used to rate any candidate system/vessel combination.

It is noted that, since only two axes are available for displaying the ERF, the functional relationship can be pictorially shown only in terms of R and the attribute variable z . In the examples where z was a function of a single variable x (continuous or discrete), it is possible pictorially to display the rating R as a function of either the attribute variable z or the system/vessel characteristic x .

A Desirable Property for Attribute Variables

Having developed a generalized and systematic procedure for formulating ERFs, it now is necessary to discuss a property of attribute variables which is very desirable and hence every effort should be made to ensure that it is accommodated when choosing an attribute variable. The purpose of this property is to facilitate a systematic development of the necessary subsystem attribute data in a convenient format which can then readily be used for evaluating candidate system/vessel combinations which are made up of either different combinations of subsystems or duplicate systems.

The desired property is the ability to establish a functional relationship for the attribute variable of any candidate system/vessel combination in terms of the attribute variable of its constituents or duplicate systems. Thus, if z_1, z_2, \dots, z_n represent the same type of attribute variable for different subsystems or duplicate systems, then the attribute variable, z , of the entire system/vessel combination is given by

$$z = f(z_1, z_2, \dots, z_n)$$

Some examples of possible attribute variables which have this property are as follows:

$$z = z_1 + z_2 + \dots + z_n, \quad \text{where}^*$$

$$z_1 = \sum_j x_j, \quad \text{where}$$

x_j may represent the duration of each maintenance action, number of parts of type i required, etc., for a subsystem or for one of the multiple systems

*More generally z_1 can be of the form $z_1 = \sum_j f(x_j)$

$$z = \text{Max} (z_1, z_2, \dots, z_n), \text{ where}$$

z - Odor level or hazard level of a subsystem

$$z = \text{Min} (z_1, z_2, \dots, z_n), \text{ where}$$

z_1 - Ability of subsystem to handle additional personnel, foreign materials, etc.

$$z = \frac{1}{n} \sum_{j=1}^n z_j, \text{ where}$$

$$z_j = e^{x_j}$$

etc.

It is noted that an attribute variable based on an average or a higher order moment, i.e.,

$$z = \bar{x} = \frac{1}{n} \sum_{i=1}^n x_i$$

or

$$z = \frac{1}{n} \sum_{i=1}^n x_i^k, \quad k = 2, 3, \dots$$

does not possess this desirable property. The approach to be followed in situations of this type is to compute and store two (or more, as required) parameters for the attribute variable of a subsystem and "pass" these parameters into the expression for the attribute variable of the system. Thus, in the above examples, one could compute and store the two values

$$n, \text{ and } \sum_{i=1}^n x_i$$

or

$$n, \text{ and } \sum_{i=1}^n x_i^k$$

The attribute variable for the entire system composed of two sub-systems can then be obtained from the above parameters as

$$z = f(z_1, z_2) = \frac{1}{n} \sum_{i=1}^n x_i = \frac{1}{n_1 + n_2} \left(\sum_{i=1}^{n_1} x_i + \sum_{j=1}^{n_2} x_j \right)$$

$$z = f(z_1, z_2) = \frac{1}{n} \sum_{i=1}^n x_i^k = \frac{1}{n_1 + n_2} \left(\sum_{i=1}^{n_1} x_i^k + \sum_{j=1}^{n_2} x_j^k \right)$$

The extension of this approach to attribute variables of the type

$$z = \frac{\sum_{i=1}^n x_i y_i}{\sum_{i=1}^n x_i} \quad \text{or} \quad z = \frac{\sum_{i=1}^n x_i y_i w_i}{\sum_{i=1}^n x_i w_i}$$

is obvious.

There are, however, attribute variables for which this property does not hold. Some examples of such functional relationships are

$$z = \sqrt{x}$$

$$z = x^2$$

etc.

The procedure to be followed in cases of this type is to preserve the raw system/vessel characteristic x of the subsystem or of one of the multiple systems and to "pass" this attribute data into the expression for the attribute variable for the entire candidate system configuration.

DEVELOPMENT OF EFFECTIVENESS ATTRIBUTE DATA

The type of system/vessel effectiveness attribute data required for the quantification of effectiveness is completely defined by the attribute variables associated with the ERFs for each elementary factor/subfactor.

However, it is noted that the formulation of the attribute variables has to take into account the availability (at a reasonable expenditure of time, effort and funding) of the required data as a basis for "measuring" the pertinent system/vessel characteristics. Thus, although formally one may view the development of ERFs and the development of effectiveness attribute data as independent efforts, in practice these two efforts need to be carefully coordinated in order to ensure a proper match between data required and data which can readily be made available. On the other hand, it is also important to ensure that the attribute variables chosen make full use of the data which is available (or can readily be made available) so that no data is "wasted" by not being used.

An effectiveness assessment of the viable candidate system/vessel combinations generally is broad in scope and will therefore encompass almost all pertinent characteristics or attributes of the available candidates. As a result, effectiveness attribute data will usually cover the entire range of physical characteristics (e.g., weight, volume, maximum height), installation characteristics (flexibility of routing piping, effect on vessel stability, vessel resource requirements, etc.), performance characteristics (effect of peak loads, ability to handle foreign objects, ability to meet effluent standards, etc.), system support (i.e., operating/maintenance) characteristics (e.g., degree of automated operation, operation and maintenance personnel time/skill/training requirements, consumables and replacement part requirements), safety/habitability characteristics (e.g., presence/likelihood/intensity of various hazards to personnel, intensity of odors/heat/noise), reliability characteristics (e.g., failure frequency, amount of redundancy, equipment ratings, equipment failure independence, ability to restore failures without interrupting system operation), etc.

Effectiveness attribute data can be system dependent only (e.g., odor, noise, maximum height, effect of foreign objects) or it can be

system/vessel dependent (e.g., effect of system on vessel stability/trim and list/range/resources, ease of routing piping, the required vessel resource supplies, suitability of system for vessel, ease of installation, system configuration redundancy).

System/vessel effectiveness attribute data can be categorized into two broad classes as being either quantitative or qualitative/subjective. Quantitative attribute data can further be classified as being continuous, discrete, or quantized (i.e., continuous data which is deliberately grouped into predetermined ranges). Qualitative/subjective data can be classified as being based on subjective comparisons to an assumed standard using a set of predetermined levels or being based on absolute subjective qualitative assignments using a set of predetermined levels.

QUANTIFICATION OF EFFECTIVENESS

The previous discussions of the effectiveness model and the guidelines for developing the various elements of this model were not addressed primarily to the problem of quantifying effectiveness, although reference was made to it as being an objective of the model. Instead, the focus of attention was the development of a framework of criteria and indications of the importance of these criteria in relation to one another. However, once the effectiveness model and the associated effectiveness attribute data have been developed, the quantification of effectiveness is, in principle, a straightforward and essentially mechanical procedure (although the computations necessary are too numerous and burdensome to be performed manually).

The key elements in quantifying effectiveness are the following:

- . The structure of the effectiveness model, i.e., the M/Es, the M/E factors/subfactors and their associated levels of subordination.
- . The weights of the M/Es and of the factors/subfactors.

- . The effectiveness rating functions.
- . The effectiveness attribute data.

The basis for the quantification is the association, with each candidate, of numerical ratings (R) for the overall effectiveness (E), for each measure of effectiveness (M/E), for each factor (F), and for each subfactor (SF), including the elementary factors/subfactors (F_e/SF_e).

These numerical ratings are indications of the degree to which each candidate satisfies the relevant criterion. In addition, each M/E , factor and subfactor, has a numerical weight (for relative importance) associated with it. Thus, the elements of the effectiveness model structure are characterized by either one or two numbers as follows:

$$\begin{array}{lcl}
 E & \longleftrightarrow & R_E \\
 M/E_i & \longleftrightarrow & R_i, W_i \\
 F_j & \longleftrightarrow & R_{ij}, W_j \\
 SF_k & \longleftrightarrow & R_{ijk}, W_k \\
 F_e/SF_e & \longleftrightarrow & R_e, W_e
 \end{array}$$

The procedure for performing the quantification is illustrated in Figure 10. Figure 10 summarizes the steps of the quantification procedure beginning with the effectiveness attribute data and ending with the overall effectiveness rating, showing the role of each element of the effectiveness model in this quantification. The different sources of effectiveness attribute data are also indicated.

The quantification starts with the elementary factors/subfactors, which have effectiveness rating functions associated with them. The use of effectiveness attribute data for a specific candidate system/vessel combination yield a rating for each elementary factor/subfactor. These ratings are multiplied by their associated weights and the sum of these

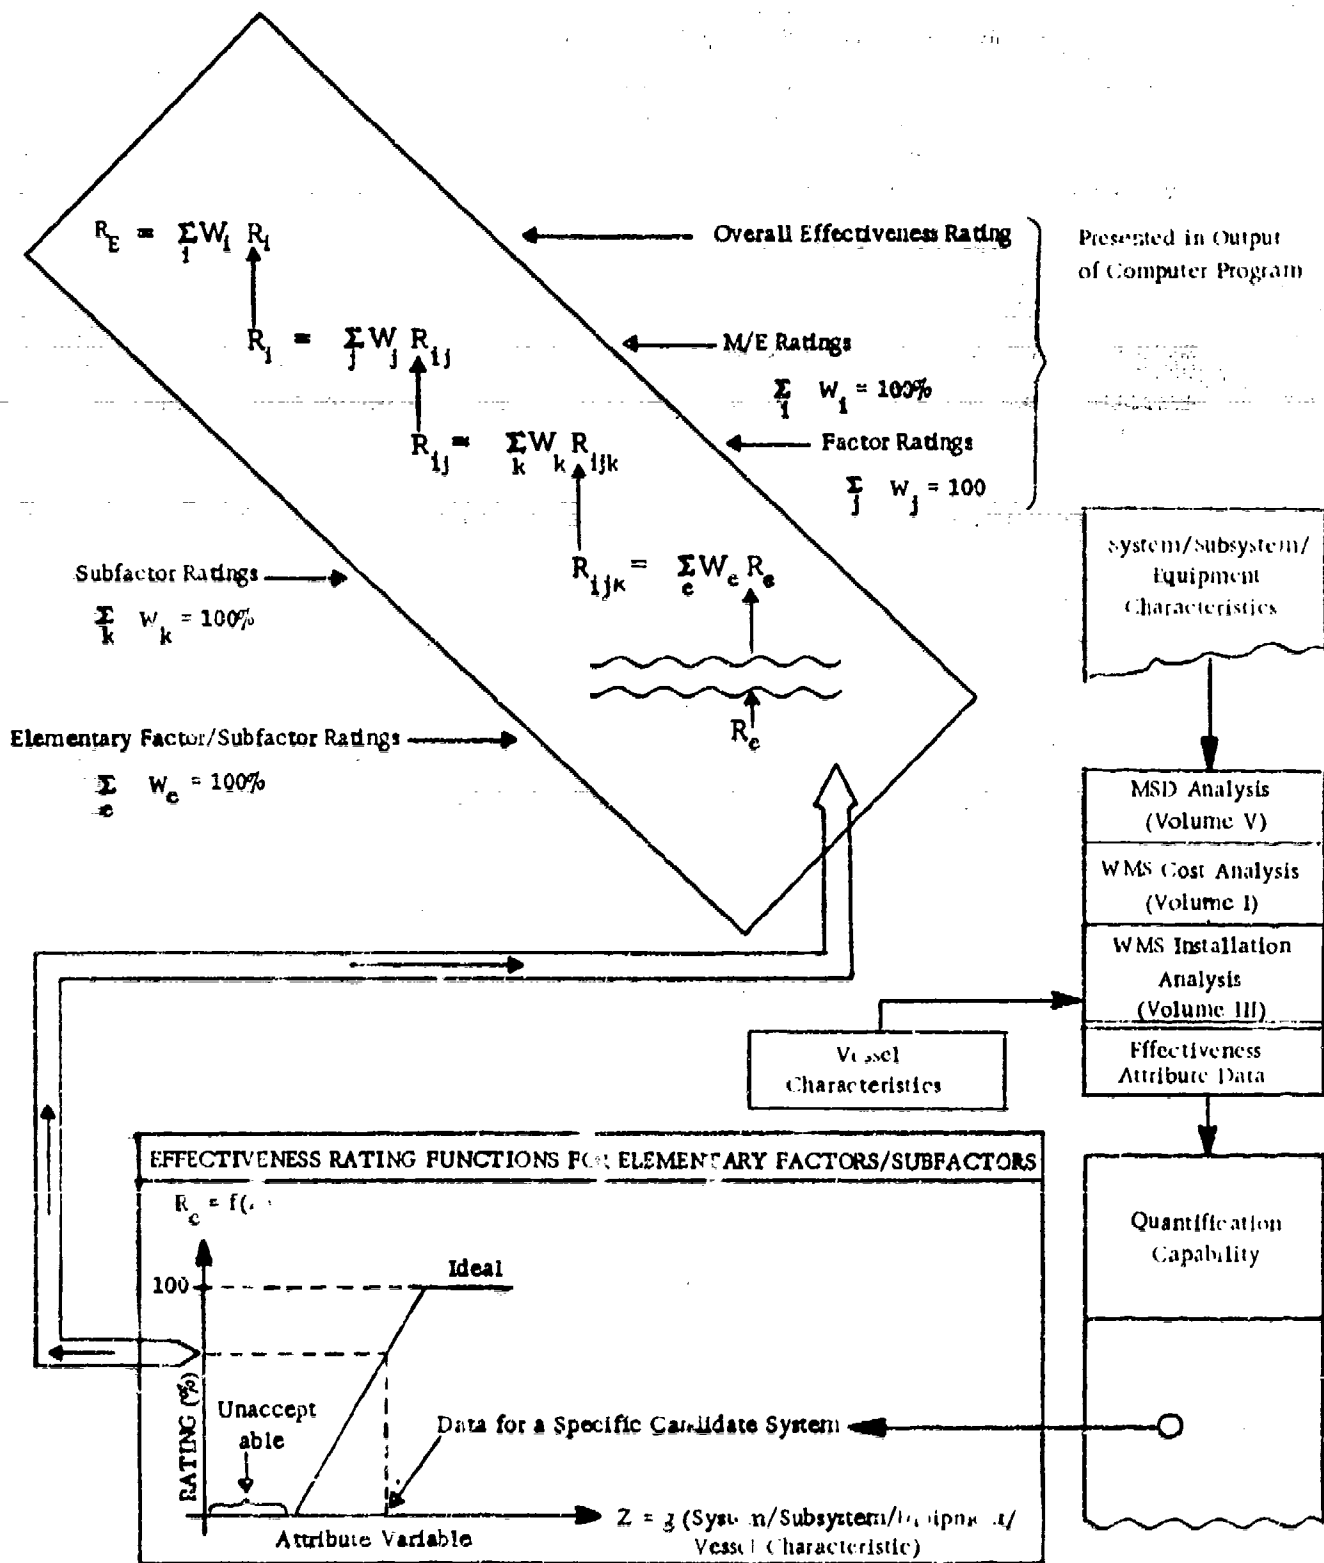

Figure 10

SUMMARY OF THE PROCEDURE FOR QUANTIFYING THE EFFECTIVENESS OF CANDIDATE SYSTEMS/VESSEL COMBINATIONS

products represents the rating for the next higher level factor/subfactor rating. Similarly, the rating for each M/E is obtained as the sum of products of the factor ratings and the associated factor weights. Finally, the overall effectiveness rating for any candidate system/vessel combination is obtained as the sum of products of the M/E ratings and the associated M/E weights. The numerical manipulations are performed by a computer program which accepts as an input the structure of the effectiveness model, the weights and the elementary factor/subfactor ratings.

SUBJECTIVE JUDGEMENT, REPEATABILITY AND VALIDITY OF RESULTS

It is noted from the foregoing discussions that subjective judgements* of the analyst play a prominent role in the development of ERFs as well as the effectiveness model structure and the associated weights. Thus, such subjective judgements become an integral part of the resulting ERFs and are therefore reflected in the effectiveness ratings of candidate system/vessel combinations for the elementary factors/subfactors (and subsequently the M/E ratings and the overall effectiveness ratings).

This raises a potentially serious question regarding the meaning and validity of the results. Thus, if the effectiveness ratings are dependent on the particular analyst conducting the study, then it might be inferred that if different decision makers conducted the analysis, different results might be obtained, i.e., the results are not necessarily repeatable across different analysts. Such an a priori conclusion regarding the seeming lack of "stability" of the results, may be alarming or disturbing and may prompt questions as to the identity and source of the "real" or "true" ERFs. It is noted that a similar issue can be raised regarding the structure of the effectiveness model and the associated weights.

* It is noted that "subjective judgement" is somewhat of a redundancy since it is questionable whether there is such a thing as "objective judgement". Thus, if the judgement were purely objective, it would imply that the same conclusion could be arrived at by logical deduction, in which case, it would not be a judgement but rather a determination and, in fact, could be performed without human intervention - e.g., by a computer.

The resolution of this apparent dilemma lies in the nature, definition, and intent of an effectiveness analysis. It will be recalled that effectiveness was defined as inherently being subjective in nature and dependent on the decision-maker, i.e., effectiveness is what the decision-maker says it is, or, effectiveness is in the eyes of the beholder.

Although this may seem like a circuitous and self-serving definition of effectiveness, it is noted that it corresponds to the manner in which decisions are made by individuals whether in their personal lives or in making consequential decisions based on highly technical information. In fact, making a decision, by definition, implies the exercise of a subjective and judgemental faculty, rather than a process of arriving at a conclusion on the basis of some objective set of rules. Thus, for example, it would not be meaningful to ask someone to decide whether system A weighs more than system B. Rather, one can be asked to determine whether system A weighs more than system B. On the other hand, one cannot determine, but rather one would have to decide, whether one system aspect is more important, better, nicer, worthier, preferred, etc., than another.

Another point to keep in mind in connection with the nature of the above dilemma is that a numerical quantity for effectiveness is not meaningful in an absolute sense but only in a relative sense. Thus, regardless of the specific numerical assignments that are made, as long as they are consistent, differences among candidate system/vessel combinations can be brought out. This is the basic purpose of an effectiveness analysis. An effectiveness analysis is not in itself a decision-making process. Instead, effectiveness analysis is a tool which the decision-maker can use to obtain the information he needs in a systematic manner and organize it in a convenient form for use by him in the decision-making process.

SOME CHARACTERISTICS AND FEATURES OF THE EFFECTIVENESS ASSESSMENT METHODOLOGY

The effectiveness assessment methodology developed as part of this study has been found to be applicable for quantifying the effectiveness of candidate system/vessel combinations at several levels of detail. It thus enables a decision-maker to compare candidates with respect to different individual aspects of effectiveness as well as the overall effectiveness. If used properly, this methodology can serve as a useful analytic tool for cost-effectiveness studies, trade-off studies, sensitivity analyses, etc. Some of the relevant characteristics and features of this methodology are as follows:

- . It can accommodate all considerations of interest to the decision-maker.
- . It synthesizes technical and objectively determined quantitative system/vessel data with qualitative system/vessel information and subjective judgements of the decision-maker.
- . It is highly flexible with respect to the range and magnitude of the problems it can accommodate. Thus, the analysis can be either very detailed and comprehensive which may be suitable for large-scale systems, or it can be much smaller in scope and less detailed as warranted by the objectives of the study and the data available.
- . It provides results at several levels of detail. Effectiveness ratings for each candidate are provided on three levels as follows:
 - .. An overall effectiveness rating
 - .. A rating for each effectiveness measure
 - .. A rating for each elementary factor/subfactor
- . It provides a means of determining the effect of changes in data, assumptions, subjective judgements, etc.

. It has been found that application of the methodology tends to clarify issues, may result in a fresh outlook and often new insights are gained, even by knowledgeable individuals who are familiar with the problem. This is due to the following aspects of the methodology:

- .. Effectiveness is defined in terms of, and directly related to, the objectives, requirements and constraints of the problem.
- .. Development of the structure of the effectiveness model requires the determination of overall assessment criteria followed by a systematic and successive breakdown of each overall criterion into constituent sub-criteria. This process results in an in-depth examination of the problem. Thus, issues which have either been overlooked or which were vague and ill-defined are identified and resolved.
- .. The need to assign a weight to designate the relative importance of each criterion encourages reflection on the basic issues pertaining to the objectives, requirements, etc.
- .. Development of effectiveness rating functions results in consideration of the relevant requirements, constraints, the type of data available, the level of detail of the analysis, and identification of the judgements used in deciding what is desirable as well as undesirable.

PROPERTIES, INTERPRETATION AND USE OF EFFECTIVENESS RATINGS

Meaning of Effectiveness Ratings

Although the overall effectiveness rating of a candidate is a number in the range of 0 to 100%, it cannot be legitimately interpreted as a probability. Instead, the rating should be interpreted as a measure of the overall

quality or "worth" of the candidate, determined as a weighted average of all considerations, i.e., the extent to which the aggregate of all the individual criteria are satisfied, weighted by the importance of each one relative to the others. Also, overall effectiveness ratings are to be used mainly for comparing candidate systems rather than in an absolute sense.

Similarly, the ratings of candidates with respect to individual M/Es are not to be interpreted as probabilities. It is especially important to keep this in mind when considering M/Es whose attributes or characteristics are usually given as probabilities.

Examples of such M/Es are "RELIABILITY" and "MAINTAINABILITY" whose ratings for a given candidate system do not have the usually used interpretation of being the probability that the system will not fail for a given period of time (Reliability) or the probability that the system will be restored within a given time interval (Maintainability). Instead, the ratings of candidates with respect to these M/Es are to be used for comparing the Reliability and Maintainability of the candidate systems. Furthermore, these M/E ratings may be based either entirely on objectively determined quantitative data, or partially on such data and partially on qualitative system information and subjective judgements. Hence, it is important to be aware of the distinction between the Reliability and Maintainability of a candidate system, which are characteristics or attributes of the system, and the effectiveness ratings of the system for the M/Es "RELIABILITY" and "MAINTAINABILITY" which include subjective judgements pertaining to such issues as what constitutes minimum acceptable and ideal levels as well as the "worth" of intermediate levels of the values for these attributes. It is noted that the Reliability or Maintainability of a candidate system, i.e., the associated probability values, may serve as an input (i.e., the attribute variable in the effectiveness rating function) in rating the system for the M/Es "RELIABILITY" and "MAINTAINABILITY", but the rating may be based on other inputs as well. If these probabilities are used as the attribute variable and a linear relationship is used as the basis for the effectiveness

rating function (ERF), then the ratings for these M/Es take on the values of the system Reliability and Maintainability characteristics.

The Effect of Weights and Levels of Subordination

Variations in overall effectiveness rating (R_E) across candidate systems are generally of smaller magnitude than variations in ratings with respect to any one M/E for different systems. Also, a variation in the value for overall effectiveness rating of a system is much more significant than a variation of the same magnitude in the system rating (R_i) with respect to any one M/E alone. The reason for these two conclusions is that the overall system effectiveness rating is obtained as a sum of the weighted system ratings with respect to the M/Es. Since the weights are all in the range of 0 to 100% (and their sum is 100%), they tend to smooth out (and sometimes swamp) the variations in M/E ratings. Thus, a very large variation in any one M/E rating must occur in order to have any significant effect on the overall effectiveness rating (if everything else is held constant). And, in order to produce a large upward (downward) variation in the overall effectiveness rating, extremely large upward (downward) variations in the ratings with respect to several M/Es must occur simultaneously (if no other variations occur).

The above conclusions can be simply illustrated with some numerical examples. Thus, a 10% change in a system rating with respect to an M/E which has a weight of 10% will result in only a 1% change in the overall effectiveness rating for that system. Similarly, even for an M/E which has a weight of 25%, a 10% change in the system rating with respect to this M/E will result in only a 2.5% change in the overall effectiveness rating for this system.

Since each M/E which is represented in the effectiveness model is generally weighted in such a way that it alone does not dominate the overall effectiveness rating, it is necessary to exercise some caution in using the overall effectiveness rating values for making decisions. This indicates

the importance of examining the individual M/E ratings of a candidate in addition to its overall effectiveness rating.

Similar conclusions can be drawn with respect to the effect of factor weights on the corresponding M/E rating and the effect of subfactor weights on the corresponding factor ratings. In addition, this effect is multiplicative when more than one level is considered. It is noted that this is not an unexpected result and it is consistent with the fact that, generally, as the number of considerations determining the outcome of a decision is increased, the influence of any one consideration on the decision must, of necessity, decrease. Thus, the overall effectiveness rating is less sensitive to variations in factor ratings than it is to similar variations in M/E ratings, etc. On the other hand, it should be kept in mind that the overall effectiveness of a system is defined in terms of the aggregate of all criteria rather than in terms of any one criterion, and the weight assignments for relative importance imply the manner in which the decision-maker is willing to trade-off one criterion (consideration) for another one.

Use of Effectiveness Ratings

Effectiveness ratings reflect the characteristics and features of the effectiveness assessment methodology discussed earlier and hence the resulting effectiveness ratings should be interpreted accordingly. Following are some guidelines for the use and interpretation of the overall effectiveness ratings as well as the ratings for each M/E.

The effectiveness assessment methodology does not in itself constitute an automated decision process which eliminates the need for a decision-maker. Instead, the effectiveness assessment methodology is a tool to be used by the decision-maker as an aid in analyzing and evaluating the candidates. As a result, the effectiveness ratings should not be thought of as automatic indicators of the effectiveness of the candidates independently of the decision-maker so that the necessity for any further considerations is eliminated. Instead, since effectiveness ratings represent the

quantitative result of the synthesis of objective and subjective system information, assumptions, requirements and the subjective judgements of the decision-maker, they should be used as a basis for making comparisons, trade-offs, analysing the effects of changes in data and/or assumptions, etc.

- . Effectiveness ratings should not be used as the basis for determining the viability of potential candidates. Such a determination must be made prior to the effectiveness analysis as part of a preliminary analysis on the basis of gross considerations, (i.e., minimum requirements) to eliminate non-viable candidates. As indicated in the discussion on the effect of weights on ratings, the effectiveness ratings are not adequate for providing the type of gross differences between candidates which are required for a preliminary analysis.
- . The effectiveness ratings are most meaningful when used and interpreted in the context of the effectiveness model. Hence, the more familiar one is with the effectiveness model, the more meaningful are the ratings.
- . Although the overall effectiveness ratings of a candidate are the most important and most often used indicator (figure of merit) of the effectiveness assessment, the individual M/E ratings for the candidate should also be examined and the reasons for either poor or high ratings should be understood. These M/E ratings may sometimes provide a rationale for a decision which overrides the importance of either a low or a high overall effectiveness rating.
- . The overall effectiveness rating of a candidate is a quantitative indication of its overall quality and hence is a convenient figure of merit which can be used as a basis for comparing and or ranking the candidates being considered.

Although the effectiveness ratings are most meaningful in a relative sense when comparing candidates against one another, rather than in an absolute sense, the rating for a candidate may be used as a rough indication of how well or how poorly the candidate is likely to fulfill the established goals and requirements. Thus, an overall effectiveness rating of 100% means complete satisfaction of all stated goals and requirements. Hence, if the overall effectiveness ratings for all candidates are low, and especially if the variation among them is small, it may be the basis for a decision that none of the available candidates are acceptable since the objectives and requirements are not likely to be met by either one of them. Prior to forming such a conclusion, one should first re-examine the effectiveness model used to ascertain that it is a reasonable conclusion. The extent to which effectiveness ratings can be used in an absolute sense rather than in a relative sense depends largely on the nature of the elementary factor/subfactor effectiveness rating functions (ERFs) used. Specifically, the important consideration in this regard is whether the rating is based on comparison of the attribute data to an absolute value or it is based on comparing all other candidates to the candidate having the largest (or smallest) value of the attribute variable, i.e., a rating based on scaling. ERFs based on comparison with an absolute value yield an effectiveness model which lends itself more readily for using effectiveness ratings as a basis of direct comparison of candidates with objectives and requirements, than do ERFs which are based on scaling procedures. On the other hand, it is usually more difficult to formulate ERFs based on comparison with an absolute value, since it generally is not obvious or easy to find a basis for establishing the level of such an absolute value.

The interpretation of effectiveness ratings should be guided by the following considerations:

- .. An elementary factor/subfactor rating of zero for any candidate does not imply that the candidate, as a whole, is unacceptable. Instead, this should be interpreted as meaning that a particular aspect of the candidate (among many others being considered) which is represented by the given ERF is not acceptable. This point is best illustrated by an ERF which has two discrete values only, namely, 0 and 100, and which usually arises from a yes or no question.
- .. Overall effectiveness ratings as well as individual M/E ratings should be interpreted in the context of a weighted average of multiple considerations. Hence, as was pointed out in the discussion on the effect of weights and levels of subordination on ratings, no one consideration can generally dominate these ratings.
- .. Since the overall effectiveness rating (or even individual M/E ratings) will generally not be sufficiently sensitive to variations in ratings for individual considerations (i.e., criteria) which are of special interest to a decision-maker, it is necessary to make special provisions for drawing attention to such individual considerations. An effective way of accomplishing this is the technique of "flagging" the criteria of interest by listing the effectiveness ratings for them in a prominent position when presenting the results of the analysis. In the candidate system/vessel combinations analyzed as part of this study, the holding capacity of each system for black and gray wastewater was thus flagged by listing the ratings for these two criteria in tables showing the results of the analysis.

COMPUTER PROGRAM FOR QUANTIFYING
THE EFFECTIVENESS OF CANDIDATE SYSTEM
VESSEL COMBINATIONS

This section of the report documents the computer program for quantifying effectiveness. It consists of the following:

- . A summary of the program features, limitations, and input requirements.
- . Instructions for preparing the input.
- . A sample problem. The sample problem consists of the viable candidate system vessel combinations included in this study. Since these candidate system/vessel combinations are discussed in detail in this volume as well as in the other volumes of this report, no further discussion of the problem appears in this section except a listing of the actual input to the computer program.
- . A description of the program including overall and detailed program flowcharts.
- . Program listings (card images).

SUMMARY OF PROGRAM CHARACTERISTICS

Output Format

A sample output of the computer program for quantifying the effectiveness of candidate systems/vessel combinations is presented in below.

Some of the important features and contents of the output are as follows:

- . A separate page is presented for each vessel and all candidate systems are listed on this page.
- . Vessel identification by user specified designation
- . Candidate system identification by user specified designation
- . Effectiveness ratings (given as a % in the range of 0 to 100 rounded to the nearest percentage point) for each candidate system on the given vessel as follows:
 - .. Overall effectiveness
 - .. Rating with respect to each measure of effectiveness (M/E) which is identified by user specified designation.
- . The weight for each M/E (given in parenthesis under each M/E as a % in the range of 0 to 100 rounded to the nearest percentage point).
- . Identification of non-viable system/vessel combinations (designated by N/A in the output).

Program Features

Some of the important features of this computer program are as follows:

- . The output is presented on a per vessel basis. For each vessel the output presents information on each candidate system (ratings for each M/E, M/E weight, overall effectiveness rating, non-viable system/vessel combinations).

- . The number of vessels and the number of candidate systems are variable input parameters for the program.
- . Vessels, candidate systems, and M/Es are identified in the output by user specified designations.
- . Masking capability for designating non-viable system/vessel combinations.
- . M/E weights must be vessel and system independent
- . Factor/subfactor weights must be system independent but may be vessel dependent. If any factor/subfactor weight is vessel independent, this fact can be conveyed to the program and only one weight need be specified.
- . Effectiveness ratings of elementary factors/subfactors are system dependent and may also be vessel dependent. If these ratings are vessel dependent this fact can be conveyed to the program and a separate set of candidate system ratings must be given for each vessel.
- . Unique identification of all input cards. In particular, every factor/subfactor weight and rating card is uniquely identified, not only with respect to level of subordination but also with respect to the M/E it belongs to and its sequence within the M/E (which conveys effectiveness model structure information to the program). Thus, if input cards are accidentally misplaced within the input deck, the computer program will rearrange them (internally) in the correct sequence.
- . Error checking capability as follows:
 - .. A check that input data is provided for all vessels (i.e., factor/subfactor weights) and all candidate systems (i.e., elementary factor/subfactor ratings).

- .. A check that all M/E weights, all factor/subfactor weights, and all elementary factor/subfactor ratings are legitimate numbers, i.e., numbers in the range of 0 to 100% rounded to the nearest percentage point.
- .. A check that the sum of all M/E weights is 100% and a check that the sum of the factor/subfactor weights at every level of subordination is 100% in every M/E.
- .. A check that candidate system/vessel ratings are provided for every elementary factor/subfactor and that no superfluous ratings are provided.

If an error is detected in the input data, the program will produce an error message, indicating which vessel, system, or M/E the error is associated with. Also, if appropriate, the punched card associated with the error will be reproduced.

Program Limitations

The program limitations with respect to the maximum values for the various input parameters are as follows:

- . Number of vessels - 20
- . Number of candidate systems - 30
- . Number of M/Es - 15
- . Number of levels of subordination within each M/E - 5
- . Number of factors/subfactors of the same level at any given level of subordination - 9

Input Requirements

The inputs to the computer program required in order to quantify the effectiveness of candidate system/vessel combinations are as follows:

- . The number of vessels (limited to 20) and the number of candidate systems (limited to 30) given on N cards.
- . Vessel identification (assigned number and name designation) given on V cards.
- . Candidate system identification (assigned number and name designation) given on S cards.
- . Identification of non-viable system/vessel combinations given on K cards.
- . M/E identification (limited to 15), including the following information and constraints (given on M cards):
 - .. Assigned M/E number
 - .. M/E name designation
 - .. M/E weights, subject to the following limitations:
 - M/E weights are system and vessel independent
 - M/E weights are given as a % in the range of 0 to 100, rounded to the nearest percentage point.
 - The sum of all M/E weights must be equal to 100%, i.e., $\sum_{\text{All M/E}} W_i = 100$
- . Effectiveness model structure identification and weights for every factor/subfactor within each M/E (given on W cards), including the following information and constraints:
 - .. The assigned number of the M/E
 - .. The current and all prior levels of subordination (limited to 5 indentures) within the M/E and the sequence number (limited to 9) at the current level of subordination of each factor/subfactor. This information is given as a single

number from 1 to 5 digits (each digit ranging from 1 to 9) and uniquely identifies each factor/subfactor as well as the structure of the effectiveness model with respect to the hierarchy of the factor/subfactor levels of subordination.

The weights for each factor/subfactor within each M/E, subject to the following limitations:

- Factor/subfactor weights must be system independent but may be vessel dependent.
- If the weight for any given factor/subfactor is vessel independent this fact can be conveyed to the computer program and only one weight is specified.
- If the weights for any given factor/subfactor are vessel dependent, they must be specified in the sequence corresponding to the vessel number assignments.
- Factor/subfactor weights are given as a % in the range of 0 to 100, rounded to the nearest percentage point.
- At any given level of subordination, the sum of all factor/subfactor weights at that level (and for each vessel if the weights are vessel dependent) must be equal to 100%, i.e.,

$$\sum w_i = 100$$

All factors/
subfactors
at the same
level

At any level of sub-
ordination and for
each vessel

Effectiveness ratings for every elementary factor/subfactor within each M/E (given on R cards), including the following information and constraints:

- .. The assigned number of the M/E
- .. The number which uniquely identifies every elementary factor/subfactor within each M/E (must match the corresponding number on the W cards).
- .. Effectiveness ratings for each elementary factor/subfactor, subject to the following limitations:
 - Elementary factor/subfactor effectiveness ratings are system dependent and may also be vessel dependent.
 - If the ratings for any elementary factor/subfactor are vessel dependent, this fact must be conveyed to the computer program by identifying the corresponding vessel number of each set of candidate system ratings (specified for each vessel separately).
 - Elementary factor/subfactor effectiveness ratings for each candidate system are given in the sequence corresponding to system number assignments.
 - Elementary factor/subfactor effectiveness ratings are given as a % in the range of 0 to 100, rounded to the nearest percentage point.

INPUT PREPARATION

The program requires seven types of input cards. They are:

- . N - Defines the number of systems and vessels applicable to the problem.
- . S - Contains the number and name of each system.
- . V - Contains the number and name of each vessel.
- . K - Contains the systems to be masked for each vessel.
- . M - Contains the measure number, weight and name.
- . W - Contains the weights applicable for each factor or subfactor for each measure.
- . R - Contains the ratings applicable for each elementary factor or subfactor for each measure.

The following paragraphs specify the preparation procedures to be observed for each input card type. A pictorial layout of all the card types, a coding sheet for type R cards, and a suggested sequence for the input are included at the end of the discussion.

N Cards

The N card contains the number of vessels and the number of systems involved in the problem. Only one card is to be prepared. This card type is required. The following table provides the rules for its preparation.

<u>Col. No.</u>	<u>Field Name</u>	<u>Enter the Following Data</u>
1-2		No entry required
3	Card Code	The letter <u>N</u>
4-8		No entry required
9-10	Number of Vessels	Enter the number of vessels (limited to 20) applicable to the problem. Right justify and zero fill.
11		No entry required.
12-13	No. of Systems	Enter the number of systems (limited to 30) applicable to the problem. Right justify and zero fill.
14-80		No entry required.

S Cards

One S card is to be prepared for each system applicable to the problem. Each system is to be assigned a unique number in the range of 01 to 30. These numbers should be assigned in the sequence the user wishes the systems to appear on the output report. System 01 will appear as row 1 and system 30 will appear as row 30. The following table provides the rules for the preparation of the S cards:

<u>Col. No.</u>	<u>Field Name</u>	<u>Enter the Following Data</u>
1-2	System Number	A unique two-character numeric in the range 01 to 30. Right justify and zero fill.
3	Card Code	The letter <u>S</u> .
4-6		No entry required.
7-34	System Number and Name	The two-character system number, a space, and the system name (25 characters) which will appear on the output report.
35		No entry required.
36-80	Full System Name	Any further description of the system required for identification purposes only. This entry is optional.

V Cards

One V card is required for each vessel applicable to the problem. Each vessel is assigned a unique number in the range of 01 to 20. These numbers are to be assigned in the sequence the user wishes the vessels to appear in the output report. Vessel 01 will appear on page 1 and vessel 20 will appear on page 20. The following table provides the rules for their preparation.

<u>Col. No.</u>	<u>Field Name</u>	<u>Enter the Following Data</u>
1-2	Vessel Number	A unique two-character numeric in the range 01 to 20. Right justify and zero fill.
3	Card Code	The letter <u>V</u>
4-80	Vessel Name	The vessel name which will appear on the output report. A maximum of 77 alpha numeric characters are allowed.

K Cards

The K card is to be used only if systems are not applicable for a specific vessel. One K card is required for each vessel where this condition exists. A maximum of 26 systems per vessel are allowed to be masked. The following table provides the rules for the preparation of this card type.

<u>Col. No.</u>	<u>Field Name</u>	<u>Enter the Following Data</u>
1-2	Vessel Number	The two-character number of the vessel within the range of 01 to 20. Right justify and zero fill.
3	Card Code	The letter K
4-5	System Number 1 (to be masked)	The two-digit system number to be masked. Right justify and zero fill if necessary.
6		No entry required.
7-80	System Number 2 through 26 (to be masked)	Continue entering the two-digit system numbers to be masked leaving a space between each. Systems must be entered in ascending numeric order.

M Cards

One M card is required for each measure applicable to the problem program. Each measure is assigned a unique number in the range 01 to 15. These numbers should be assigned in the sequence the user wishes the measures to appear on the output report. Measure 01 will appear in the leftmost column and measure 15 will be the rightmost column. The following table provides the rules for the preparation of the M cards.

<u>Col. No.</u>	<u>Field Name</u>	<u>Enter the Following Data</u>
1-2	Measure Number	A unique two-character numeric in the range 01 to 15. Right justify and zero fill.
3	Card Code	The letter <u>M</u>
4-6	Weight	The weight of the measure. Must be numeric. Right justify and zero fill.
7-16	Measure Name	The measure name that will appear on the output report.
17-26	Measure Name (continued)	This may be continued in columns 17-26. Col. 7-16 will appear as the first line and col. 17-26 will appear as the second line of the heading.
27		No entry required.
28-80	Full Measure Name	Any further description of the measure required for identification purposes only. This entry is optional.

W Cards

One W card is prepared for each factor and subfactor within each measure. A maximum of 10 weights may be entered on a card. If there are more than 10 vessels in the problem, and therefore more than 10 weights, a continuation card is to be used. The maximum number of vessels (weights) allowed is 20.

Each factor/subfactor is assigned a unique (within a measure) Factor Code Number. Both the weights and ratings are assigned the same factor code number in each measure. The following conventions are used in assigning the numbers:

- Factors are identified by a single digit number from 1 to 9.
- Subfactors are identified by a multiple digit number, the first of which is the factor digit.

A special feature of the type 'W' card is the Duplicate Code. The use of this code will simplify the preparation of these cards by the user. This code is used only when all the weights for a factor or subfactor are identical (for all vessels). When used, the letter X is entered in column 40 and the weight is entered in columns 41-43. No additional weights are to be entered when the duplicate code is entered in column 40. Additionally, if more than 10 vessels are involved in the problem and continuation cards are being used, the continuation cards are not required when the duplicate code is used.

The use of the continuation card, mentioned above, is accomplished in the following manner. The weights of the first 10 vessels are entered on the input form and a 1 is entered in column 80. The weights of the remaining vessels are entered on the next line of the input form and a 2 is entered in column 80. The information contained in columns 1 through 37 is identical on both lines of input.

The following table provides the rules for the preparation of the W card.

<u>Col. No.</u>	<u>Field Name</u>	<u>Enter the following data</u>
1-2	Measure Number	The measure number previously assigned on the M card. Right justify and zero fill.
3	Card Code	The letter <u>W</u> .
4-8	Factor Code Number	The number assigned using the rules described above. <u>Left</u> justify. It is not necessary to zero fill.
9-37	Description	The name of the factor/subfactor. This is for identification purposes only.
38-39		No entry required.
40	Duplicate Code	An X if all the weights are identical.
41-43	Weight (Vessel 1)	The weight for vessel 1. Must be numeric. Right justify and zero fill. If an X has been entered in column 40 no additional entries are needed.
44		No entry required.
45-79	Weights (Vessels 2-10)	The weights for each successive vessel. Must be numeric, right justified and zero filled. Each 3 position weight is separated from the next weight by a blank space.
80	Continuation Code	Only to be used if more than 10 vessels are involved in the problem. Enter a 1 on the first card and a 2 on the second. Submit only 1 card and do not make an entry in col. 80 if an 'x' has been entered in col. 40.

R Cards

This input data is prepared in a similar manner to the type W cards previously discussed. One important difference is that Type R cards are prepared for elementary factors/subfactors only. There is no input preparation for non-elementary factors/subfactors.

The ratings applicable to a problem run are normally system dependent. A maximum of 10 ratings can be entered on a single card. The maximum number of systems allowed by the program are 30, therefore allowing the user to prepare up to 3 cards per factor/subfactor. A continuation code is used to handle more than 10 systems. The ratings applicable to the first 10 systems are entered on the first card and a 1 is entered in column 80. The ratings of the 11th through 20th systems are entered on the second card and a 2 is entered in column 80. The ratings of the remaining systems are entered on the third card and a 3 is entered in column 80.

It is possible that in a particular problem some of the ratings will be both system and vessel dependent. The program allows for this possibility. For this situation, the user must enter the applicable vessel number in columns 38-39. The ratings are entered in the normal manner and continuation cards may be used if necessary.

The table on the following page provides the rules for the preparation of the type R card.

CODING SHEET FOR TYPE R CARD :

SYSTEM/VESSEL RATINGS FOR ELEMENTARY FACTORS/SUBFACTORS

M #	R	Code #	Factor/Subfactor Name	V #	System Ratings										10				
					1	2	3	4	5	6	7	8	9						
1	R																		
2	R																		
3	R																		
4	R																		
5	R																		
6	R																		
7	R																		
8	R																		
9	R																		
10	R

12	R																		
13	R																		
14	R																		
15	R																		
16	R																		
17	R																		
18	R																		
19	R																		
20	R																		

<u>Col. No.</u>	<u>Field Name</u>	<u>Enter the Following Data</u>
1-2	Measure Number	The measure number previously assigned on the M card. Right justify and zero fill.
3	Card Code	The letter <u>R</u> .
4-8	Factor Code Number	The number assigned using the rules described above. <u>Left justify</u> . It is not necessary to zero fill.
9-37	Description	The name of the factor/subfactor. This should match the description entered on the corresponding W card.
38-39	Vessel Number	Use only when ratings are vessel dependent. Enter the appropriate vessel number as previously assigned on the V cards.
40		No entry required.
41-43	Rating (System 1)	The rating for system 01 as designated on the S cards. Must be numeric. Right justify and zero fill. A rating must be entered for each system.*
44		No entry required.
45-79	Ratings (Systems 2-10)	The ratings for each successive system. Must be numeric, right justified, and zero filled. Each 3-position rating is separated from each other by a blank space.
80	Continuation Code	Use only when more than 10 systems are used in the problem. Enter a 1 on the first card, a 2 on the second, and a 3 on the third if there are more than 20 systems. Do not make an entry in this field if there are 10 systems or less.

* Ratings must be given even for systems which do not apply to the given vessel, i.e., non viable system/vessel combinations which are specified on the K cards. Since these ratings are eventually masked, any legitimate rating number may be used (i.e., any number between 0 and 100). A rating of 0 is suggested for convenience.

269

270

Input Sequence

The following recommended sequence (shown on the following page) will provide the user ease in locating any invalid cards rejected by the edit module (step 2). The user, may, however, select any alternate sequence he may find more practical.

Card Type N - Function - sets the number of systems and vessels applicable for the particular run.

Card Type S - Function - contains the abbreviated system name (25 characters) which will appear on the output report.

Card Type V - Function - contains the vessel name which will appear on the output report.

Card Type K - Function - masking non-viable candidate systems on a vessel basis.

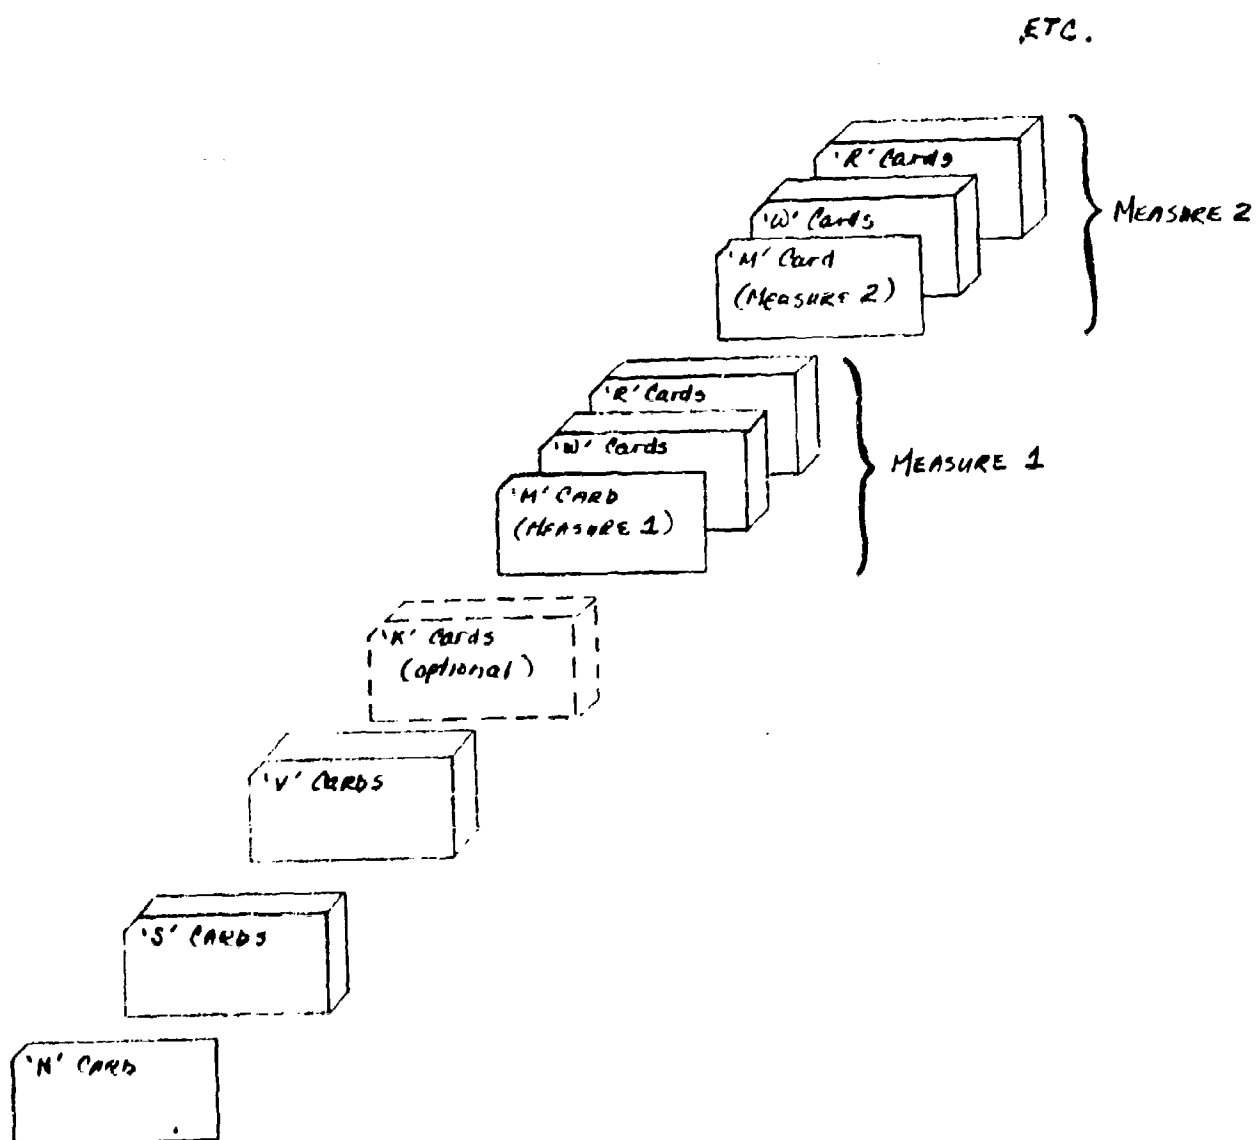

Following these parameter and formatting cards, the factors and sub-factors are to be input. These cards should be grouped by measure.

Card Type M - Function - contains the abbreviated measure name (10 characters) which will appear on the output report. The card also contains the measure weight. One 'M' card is required for each measure.

Card Type W - Function - contains the weights (by vessel) for each factor, subfactor. Cards should be in factor sequence.

Card Type R - Function - contains the ratings (by system) for each factor, subfactor. Cards should be in factor sequence.

RECOMMENDED SEQUENCE OF INPUT DATA

SAMPLE PROBLEM

The sample problem included in this section consists of the 18 viable candidate systems for the six vessels included in this study. This section contains a listing of the input (card images), a pictorial layout of the job stream, a list of the actual JCL, and the resulting output report.

Job Stream

This section contains both a schematic diagram (see following page) and a card image of the actual Job Control Language (JCL) used to run the sample problem. The user prepared input (part of Step 1) should be sequenced as previously described.

JOB STREAM INPUT

Actual JCL

```
//STEP1 EXEC SORT,PARM.SORT='CORE=060000,MSG=AP',REGION=70K
//SYSOUT DD SYSOUT=A
//SORTIN DD *,DCB=BLKSIZE=80
```

{ USER PREPARED INPUT

```
/*
//SCRTWK01 DD UNIT=SYSDA,SPACE=(CYL,(2,1))
//SORTWK02 DD UNIT=SYSDA,SPACE=(CYL,(2,1))
//SCRTWK03 DD UNIT=SYSDA,SPACE=(CYL,(2,1))
//SORTWK04 DD UNIT=SYSDA,SPACE=(CYL,(2,1))
//SCRTWK05 DD UNIT=SYSDA,SPACE=(CYL,(2,1))
//SORTWK06 DD UNIT=SYSDA,SPACE=(CYL,(2,1))
//SCRTCLT DD DSN=&FACTOR1,DISP=(NEW,PASS),UNIT=SYSDA,
//          DCB=(RECFM=FB,LRECL=80,BLKSIZE=800),SPACE=(CYL,(2,1))
//SCRT.SYSIN DD *
SORT FIELDS=(1,2,A,4,5,C,38,2,A,3,1,D,80,1,A),FORMAT=BI
/*
```

```
//STEP2 EXEC PGM=CGWM1
//STEPLIB DD DSN=BIDS.TEST,DISP=SHR
//SYSOUT DD SYSOUT=A
//SYSOUT DD SYSCUT=A
//PRINTER DD SYSOUT=A,DCB=BLKSIZE=1330
//FACTORS DD DSN=&FACTOR1,DISP=(OLD,PASS),
//          DCB=(RECFM=FB,LRECL=80,BLKSIZE=800)
//SYSIN DD DSN=BIDS.CLYSLAST,DISP=SHR
```

```

PROGRAM DESCRIPTION

The computer program for quantifying the effectiveness of candidate system/vessel combination is written in ANSI COBOL. It consists of two sorts and two program modules.

The first sort reads as input the complete user prepared data for the problem. The output of the sort is a temporary disk data set which is deleted at the end of the entire run. This data set (&FACTOR1) is input into the first program module, the edit.

The edit program module (CGWM1) reads each card image from the temporary data set. The first edit performed is on the type of input. Column three of the input data prepared by the user contains an alphabetic character indicating the type of input. If the entry in the input card is different than those allowed, the error message 'Invalid Card Type' and the card image is printed on the reject report.

Numerous edits are performed on the factors and subfactors contained in the weight and rating input cards. Each factor or subfactor is tested for numeric and is also checked to be in the legitimate range of zero to one-hundred. If these tests are failed, the error messages 'Non-Numeric Factor', 'Factor Less than Zero', or 'Factor Greater than One-Hundred' are output along with the image of the card. Each rating card, in addition to the above editing, must also match a weight card, which is processed immediately prior to it. If the rating card does not match, the error message 'Unmatched Rating Card' and the card image are output. When the level of the weight factors/subfactors changes, no rating factor/subfactor is required. An additional edit is performed to check this and the error message 'Invalid Rating Card' is printed if a rating card is present.

One final edit is performed on the weight card factors and subfactors. As each card is processed, the weights are accumulated. When

the factor/subfactor level changes, the accumulated weights are checked to determine if they add to one hundred. If they do not, the error message 'Factors Not 100' is printed along with the related measure number, vessel number, and level.

At the conclusion of the edit module, the temporary data set which was used as input, is resorted and a second temporary data set (&FACTOR2) is created. This data set becomes the input file to the calculation module (CGWM2). Although the edit module performs most of the editing functions, a few additional edits are performed in this module. These edits are performed before the calculations are begun and, if any edit fails, the module is aborted. The following areas are edited:

- . Measure Cards
- . System Cards
- . Vessel Cards

a) Measure Card Editing (Card Type M)

The weight assigned to each measure is edited for the following criteria. It must be numeric, less than or equal to 100, and greater than or equal to zero. If any of these edit tests are failed, an appropriate message is printed and the module aborted. The measure weights are accumulated, and after all of the input data has been processed, the accumulated weight is checked to see if it is one-hundred. If it is not, the module is aborted.

The limit on the number of measures allowed in the program is 15. The measure number on each measure card processed is checked. It must fall in the range of 01 to 15. An error message is printed and the run aborted if it is not.

b) System Card Editing (Card Type S)

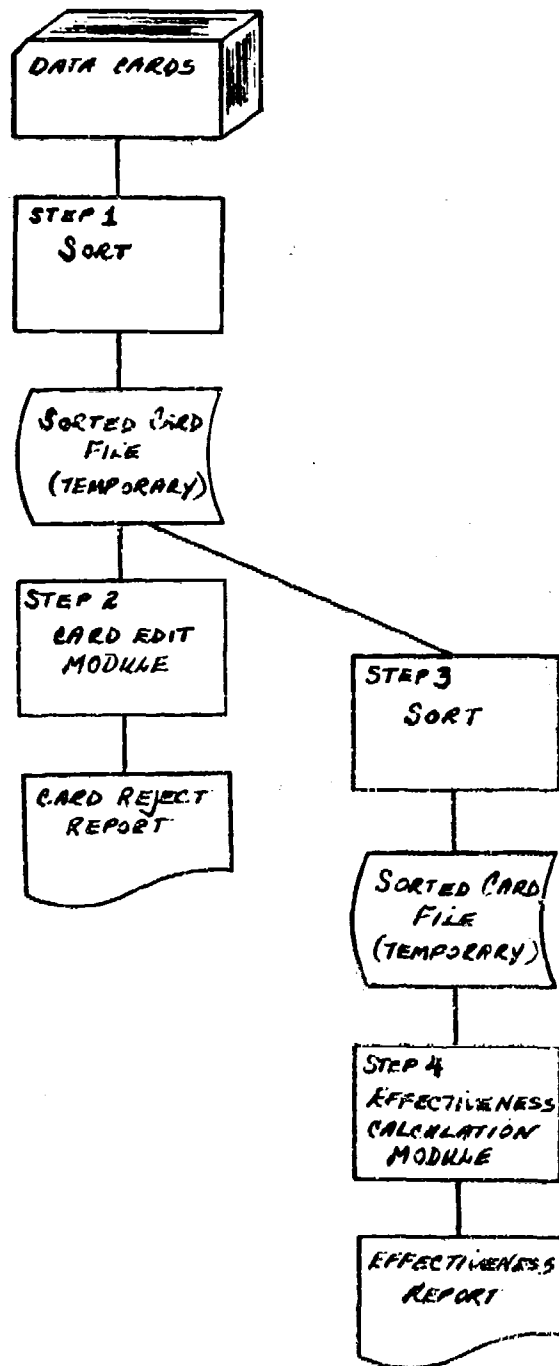

The maximum number of systems allowed in the program is 30. The system number on each system card processed is edited. It must fall within the valid boundaries of 01 to 30. If it does not, an error message is printed and the module aborted.

c) Vessel Card Editing (Card Type V)

A similar type edit is performed on vessel cards as is performed on the system cards. The maximum allowable number of vessels is 20. If the vessel number on the vessel card is outside the range of 01 to 20, an error message is printed and the run aborted.

The calculation module initially reads all of the input data, performs the above edits, and tables the data read. The module then begins the calculation of the effectiveness of each system. This is performed for each measure and for the overall effectiveness for each system for each vessel. The measures of effectiveness are calculated by system within vessel. Each vessel appears on a separate page. If a system is not applicable for a particular vessel, the measures of effectiveness ratings are masked out and the symbol N/A will be printed instead of the rating for the measure of effectiveness.

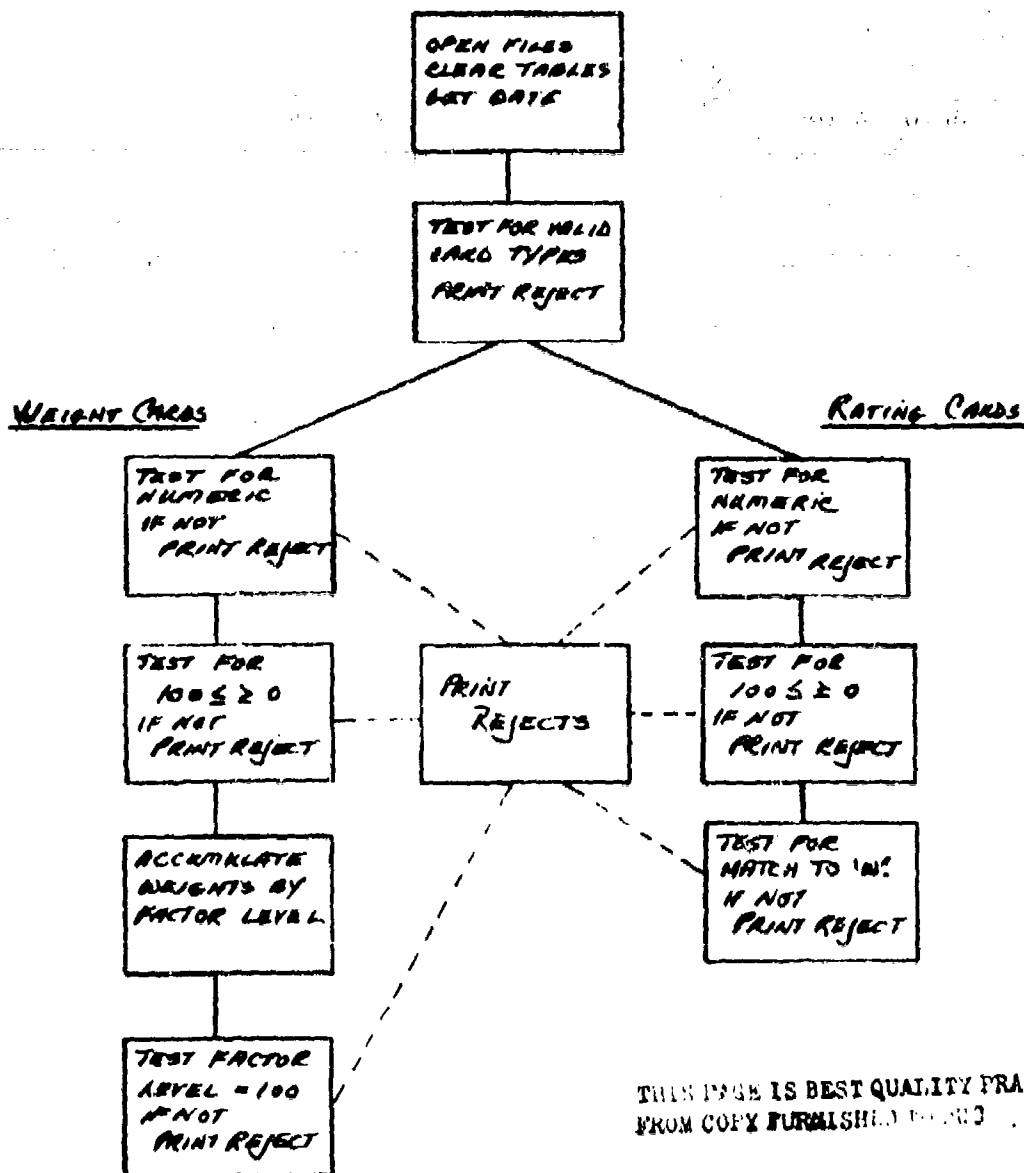

OVERALL PROGRAM FLOWCHART

Edit Module

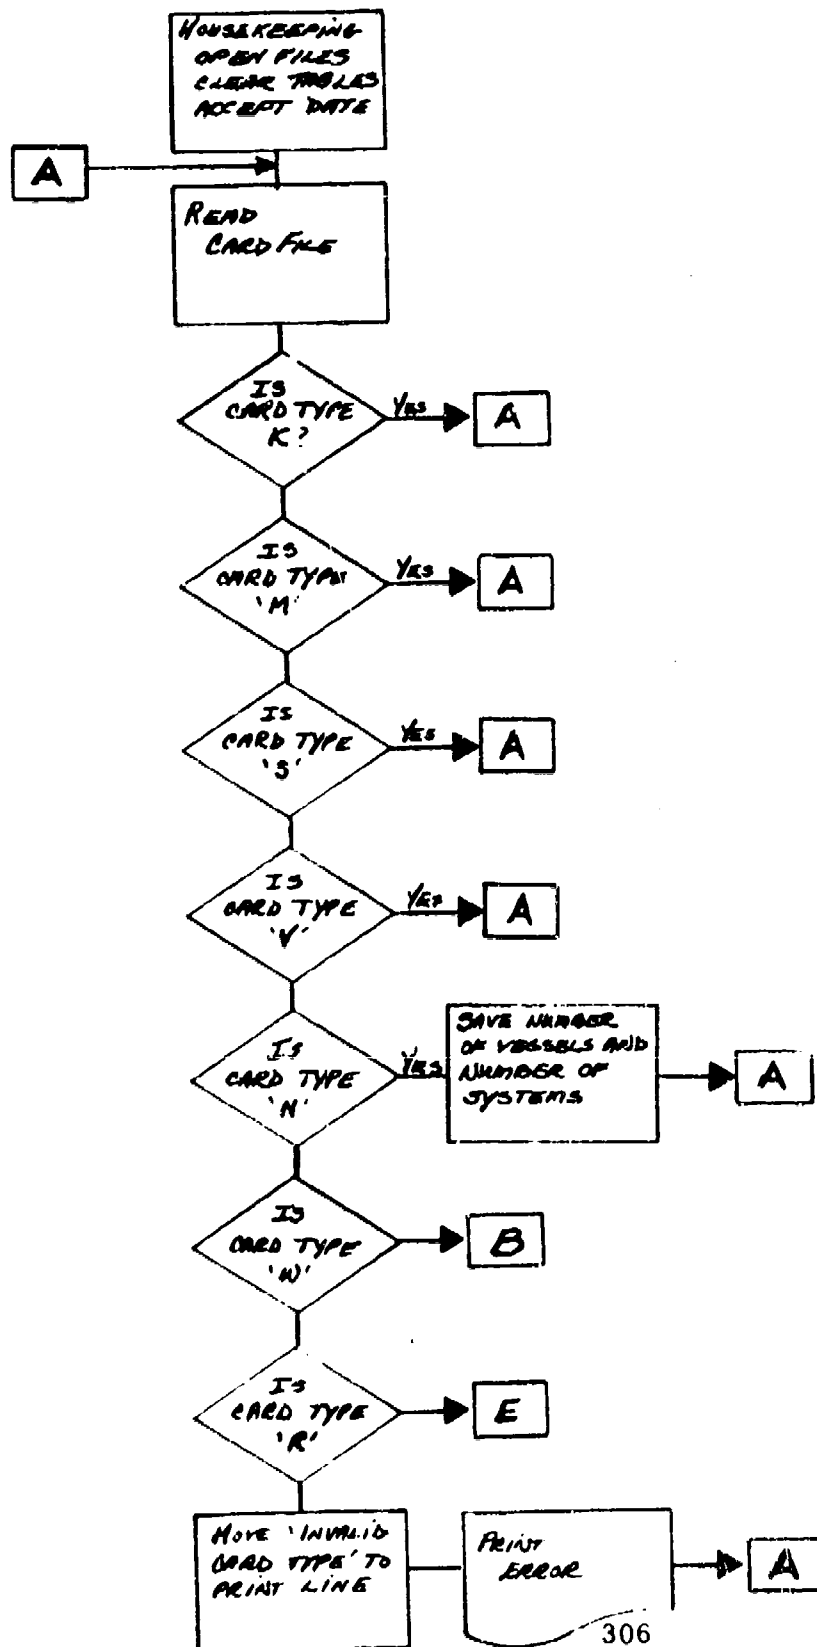

As described on the preceding pages, the Edit Module performs almost all of the editing required on the input. The following flowcharts illustrate processing on a subroutine (overall) and detailed level.
